Systematic review of involving patients in the planning and development of health care

Mike J Crawford, Deborah Rutter, Catherine Manley, Timothy Weaver, Kamaldeep Bhui, Naomi Fulop, Peter Tyrer

Abstract

**Objective** To examine the effects of involving patients in the planning and development of health care.

**Data sources** Published and grey literature.

**Study selection** Systematic search for worldwide reports written in English between January 1966 and October 2000.

**Data extraction** Qualitative review of papers describing the effects of involving patients in the planning and development of health care.

**Results** Of 42 papers identified, 31 (74%) were case studies. Papers often described changes to services that were attributed to involving patients, including attempts to make services more accessible and producing information leaflets for patients. Changes in the attitudes of organisations to involving patients and positive responses from patients who took part in initiatives were also reported.

**Conclusions** Evidence supports the notion that involving patients has contributed to changes in the provision of services across a range of different settings. An evidence base for the effects on use of services, quality of care, satisfaction, or health of patients does not exist.

Introduction

Over the past 20 years, governments throughout western Europe and North America have encouraged patients to contribute to the planning and development of health services. In England and Wales the involvement of patients is central to current efforts to improve the quality of health care. Underlying these changes is the belief that involving patients leads to more accessible and acceptable services and improves the health and quality of life of patients. This view is endorsed by government policy, which states that involving patients leads to "more responsive services and better outcomes of care."

Several authoritative guides to different ways to involve patients in the planning and development of services have been published. Involving patients is becoming less discretionary and more compulsory for the providers of services, but engaging patients is not an easy task, and no consensus on which methods are most effective under different circumstances exists. We therefore carried out a literature review to examine the effects of involving patients and the circumstances in which these take place.

Methods

We identified papers for possible inclusion by combining searches of electronic databases, hand searches of reference lists of papers, contact with experts in the field and groups of patients belonging to the national Patients Forum, and a purposive hand search of grey literature held at the King's Fund and Department of Health libraries. Electronic databases searched comprised medical literature (Medline from 1966, Embase from 1988, PsychINFO from 1967), nursing literature (CINHAL from 1982), healthcare management literature (HMIC and HELMIS from 1983), and grey literature (EAGLE from 1980). We used medical subject headings and free text searches related to "user involvement"—combinations of "client," "consumer," "patient," "user" and "empowerment," "involvement," "participation," "representation," for those related to planning and delivering health services—combinations of "health," "health care," "health services," "service," "welfare" and "delivery," "development," "organisational delivery," "organisational change," "organisational development," "planning," "provision." Searches were restricted to papers published in English between January 1966 and October 2000.

**Criteria for selection** We included papers that described the involvement of patients, defined as the "active participation in the planning, monitoring, and development of health services of patients, patient representatives, and wider public as potential patients." We included all papers that described the effects of involving patients in the planning and development of health care. Excluded papers described patient involvement in other activities such as research, community development, health promotion, self management and self help, and the role of doctors and patients in determining individual treatment choices. We also excluded papers that described the measurement of patient satisfaction or patient preferences without describing how this information was used to help development of the service.

Two researchers (DR and CM) independently examined titles and abstracts of papers to decide if the
full text articles should be obtained. Where there was disagreement, this was resolved through consultation with a third reviewer (MJC). Full text articles were then examined and additional papers excluded if a more detailed examination showed that papers did not fit the study’s aims.

**Qualitative analysis**

When reading articles for inclusion in the review each reviewer (DR, CM, or MJC) completed an annotation form. This allowed the reviewer to describe the nature of the evidence contained in the paper (quantitative research, qualitative research, review of previous literature, case study, expert opinion), the context of involvement (geographical setting, nature of the service, and patient group), the method used (for example, survey, patient representation at meetings), and finally whether or not outcomes of involvement were reported. Classifying papers in this way allowed us to develop a series of categories represented by keywords that were entered onto a bibliographic database and subsequently used to search for papers illustrating particular themes. An initial examination of findings showed that most papers that presented outcomes of involvement were case reports from workers involved in projects. Our approach to data analysis was therefore restricted to a narrative account of outcomes of involving patients and the nature of the evidence used to support these claims. Because no system for rating the quality of information in case reports exists, we could not assign quality ratings to the papers we included.

**Results**

We found 337 studies about involving patients in the planning and development of health care. Of these, we excluded 294 (87%) because they did not describe the effects of involvement.

Accepted studies included 42 papers (12%) that described the effects of 40 initiative involving patients (table 1). Of these, 31 were case reports, five were the results of surveys, three examined records of meetings, and three described the findings of action research. Four reports clearly described the use of qualitative research methods. We did not find any reports that used comparative or experimental research methods.

Papers described a range of different models of involvement applied in a range of settings in hospitals and the community. The different effects of involving patients and the nature of the evidence to support these findings are summarised in table 2. We were unable to identify any reports that investigated the effects of involving patients on the health, quality of life, or satisfaction of those using services.

**Changes to services**

Among the most frequently reported effects of involving patients was the production of new or improved sources of information for patients. Other changes included efforts to make services more accessible through simplifying appointment procedures, extending opening times, improving transport to treatment units, and improving access for people with disabilities.

Several reports describe new services being commissioned as a result of the requests of patients, including advocacy initiatives aiming at improving opportunities for employment, complementary medicine, crisis services, and fertility treatments.

Two reports describe how involving patients led to proposals to close hospitals being modified or abandoned.

**Other effects of patients being involved**

Eighty reports state that initiatives had a more general effect on organisational attitudes to involving patients. These included comments that staff attitudes to involving patients became more favourable and that the culture of organisations changed in a way that made them more open to involving patients. Some projects resulted in further initiatives aimed at strengthening the involvement of patients. Concerns were also expressed by researchers who found evidence that involving patients was used to legitimise decisions that would have been made whether or not patients supported them.

One report concluded that the decision making process was slower because patients were involved.

**Overall impact of involvement**

Attempts to gauge the overall impact of involving patients have been made by conducting surveys of participants and retrospectively examining records of meetings. A survey of the leaders of public involvement initiatives of Health Systems Agencies in the United States in 1980 asked respondents to judge the effects of involving patients. Of the 154 (76%) who replied, 75% (116) said that involving patients had improved the quality of health services and 46% (71) that it had led to improvements in people’s health. Of 63 patient participation groups in primary care settings surveyed in Britain in the mid-1980s, 32 (52%) were able to provide details of at least one change that groups had initiated.

Facilitated meetings between workers in primary care and patients with diabetes in 17 primary care centres in Stockholm in the mid-1980s generated 196 plans for improving patient care. Eighteen months later the extent to which plans had been implemented was evaluated. 70% (137) of plans had been implemented. A retrospective examination of records from meetings of five mental health forums in Kent, United Kingdom, identified 57 concerns raised by groups over a two year period. Of these, 22 (39%) resulted in a response from providers of services that was judged acceptable.

**Discussion**

A review of more than 300 papers on involving patients in the planning and development of health care found that few described the effects of this

*A form of quality assessment by service users. †Two separate case studies in one report.
process. Those that have done so are generally case studies where project administrators running projects have commented on what the project achieved. Although these reports support the view that involving patients has contributed to changes to services, the effects of involvement on accessibility and acceptability of services or impact on the satisfaction, health, or quality of life of patients has not been examined.

We found some of the most informative material for this review in grey literature. While we made considerable effort to locate grey literature, the methods we used would not have identified all reports on this subject, especially those from outside the United Kingdom. Another potential problem in interpreting the results is that publication bias may favour the publication of reports from initiatives that were judged to be successful.

Several factors may account for our central finding, the limited amount of information about the effects of involving patients. The aims of involving patients have always been broader than just improving the quality of health care. Involving patients has been viewed by many as a democratic or ethical requirement: because patients pay for services they have a right to influence how they are managed. An alternative view is that involving patients is not intended to devolve power to patients but to legitimise the decisions of policy makers and administrators. It is argued that through consulting with users of health services, support for decisions that would otherwise be unpopular can be obtained. Such aims imply that establishing mechanisms for involving patients should be seen as an end in itself rather than as a means of improving the quality of services. However, initiatives that fall short of bringing about changes to services are not in keeping with the aims of current policy or patients.

The effects of involving patients are likely to be complex, affecting different aspects of services in different ways. The views of patients are among many factors that influence change in health services, and providers of health care remain the final arbiter of how much weight is attached to patients' views. Separating out change specifically attributable to the participation of patients is a difficult task. Despite these problems, possible effects, amenable to formal evaluation, of involving patients have been discussed, including extent of use of the service, satisfaction, and quality of life. Patients' involvement is not without its costs, and including outcome measures in future evaluations of involving patients could enable comparisons of different approaches and evaluation of the effects of suggestions made by patients.

### What is already known on this topic

Involving patients in planning and delivering health services is recommended as a means of improving the quality of services

Methods for engaging with patients have been considered in depth, but the effects of involving patients are less clear

### What this study adds

Few studies have explored the effects of involving patients

Involving patients has contributed to changes in service provision, but the effects of these on quality of care have not been reported

### Conclusions

Patients have contributed to the planning and development of services across a range of settings, but the effects of this process on the quality and effectiveness of services are unknown. This absence of evidence should not be mistaken for an absence of effect. Healthcare providers may be increasingly required to demonstrate that they involve patients in the planning process, but they will also continue to be accountable for the decisions they make. A better evidence base may be necessary to persuade providers to place greater emphasis on patients' views when making decisions about services.

We thank members of a steering group that oversaw the project, groups from the Patients Forum and others who responded to our request for grey literature, and staff at the Department of Health, Kings Fund, and Imperial College for their help in identifying grey literature.

Contributors: MC, TW, KB, NF, and PT conceived the study, MC, DR, and CM collected and analysed data. MC, DR, CM, TW, KB, NF, and PT contributed to analysing data, interpreting the results, and writing the paper. MC is the guarantor.

Funding: The project was funded by a grant from London Region NHS Executive, Organisation and Management Research and Development Programme.
