*Clostridium difficile* is the most common cause of antibiotic-associated diarrhoea worldwide. Over the past 10 years, the incidence and severity of disease have increased in North America and Europe due to the emergence of a hypervirulent clone designated PCR ribotype 027. In this study, we sought to identify phenotypic differences among a collection of 26 presumed PCR ribotype 027 strains from the US and the UK isolated between 1988 and 2008 and also re-evaluated the PCR ribotype. We demonstrated that some of the strains typed as BI by restriction endonuclease analysis, and presumed to be PCR ribotype 027, were in fact other PCR ribotypes such as 176, 198 and 244 due to slight variation in banding pattern compared to the 027 strains. The reassigned 176, 198 and 244 ribotype strains were isolated in the US between 2001 and 2004 and appeared to have evolved recently from the 027 lineage. In addition, the UK strains were more motile and more resistant to most of the antibiotics compared to the US counterparts. We conclude that there should be a heightened awareness of newly identified PCR ribotypes such as 176, 198 and 244, and that they may be as problematic as the notorious 027 strains.

INTRODUCTION

*Clostridium difficile* is a Gram-positive, anaerobic, spore-forming bacillus that is the causative agent of *C. difficile* infection (CDI) (Bartlett, 1994). CDI is often caused after broad-spectrum antimicrobial therapy, which disrupts the barrier effect of the endogenous intestinal microflora allowing *C. difficile* spores to germinate, colonize the gastrointestinal tract and produce toxins, which causes tissue damage (Just et al., 1995, 2001). Antibiotic resistance is likely to be important in infection, as it would provide *C. difficile* a competitive growth advantage in the gut of patients after antibiotic treatment (Delaney et al., 2007). Colonization is also an important step in *C. difficile* pathogenesis, which involves various determinants including surface-layer proteins, adhesins (P47, Cwp66 and Fbp68) (Calabi & Fairweather, 2002; Hennequin et al., 2003; Waligora et al., 2001) and flagella, which have been implicated in adherence of *C. difficile* to caecal mucus in axenic mice (Tasteyre et al., 2001). Flagella have multiple roles in virulence of other enteric pathogens including motility through the viscous intestinal mucosa, chemotaxis, protein secretion and interaction with the innate immune system (Feuilliet et al., 2006; Lee et al., 1986; Milton et al., 1996; Moulton & Montie, 1979; Pruckler et al., 1995).

In the last few years, the appearance of highly virulent and epidemic *C. difficile* strains has significantly changed the epidemiology of CDI in North America and Europe (Kuijper et al., 2007; Pépin et al., 2005). This is largely due to the emergence of a clonal lineage referred to using different typing methods as BI [restriction endonuclease analysis (REA)], NAP1 (PFGE), 027 (PCR ribotype) (Killgore et al., 2008) and different clusters [multiple-locus variable-number tandem-repeat analysis (MLVA)] (Eckert et al., 2011). The hypervirulent NAP1 types can be subtyped as NAP1, NAP1a or NAP1c variants, whereas there are at least 23 variants of the REA types, BI-1 to BI-23 (Killgore et al., 2008). MLVA can subtype in different clusters (Eckert et al., 2011). All these strains are invariably classified as toxinotype III by toxinotyping (Rupnik et al., 1998).

The first documented PCR ribotype 027 was described as an isolate from a Parisian hospital in 1985 (Popoff et al., 1988). It was occasionally isolated in the 1990s in the US until major outbreaks of 027-related CDI emerged in 2003 (Morris et al., 2002; Redelings et al., 2007; Ricciardi et al., 2007). There has been a threefold increase in CDI in the elderly, largely as a result of the emergence of the 027 strains during 2000–2005 (Jagai & Naumova, 2009). In the UK, major outbreaks emerged in 2006 where the PCR ribotype 027 was identified. The proportion of 027 strains...
isolated in UK hospitals rose sharply from 25.9% to 41.3% between 2005 and 2008 (Brazier et al., 2008). Patients infected with 027 strains have more severe diarrhoea, higher mortality and more recurrences (Goorhuis et al., 2007; Hubert et al., 2007; Loo et al., 2005; Mooney, 2007; Redelings et al., 2007).

A whole genome comparison method using microarrays (comparative phylogenomics) demonstrated that most NAP1/BI/027 isolates formed a single clonal lineage, termed the hypervirulent clade (Griffiths et al., 2010; He et al., 2010; Sebaihia et al., 2006). However, there were exceptions: a single BI-9 (NAP1c) clustered outside the clonal lineage (He et al., 2010; Stabler et al., 2006), identified later as PCR ribotype 001 (He et al., 2010), and BI-14 (NAP1) was an outlier to the hypervirulent clade (Stabler et al., 2006). Interestingly, a previous report showed that not all NAP1 isolates are PCR ribotype 027. For example, strain CA10 was NAP1, but PCR ribotype 019 (Killgore et al., 2008). MLVA has been used to discriminate between isolates with identical PCR ribotypes belonging to types 001, 017 and 027 (van den Berg et al., 2007). Given that many of the PCR-ribotyped C. difficile isolates in the US and UK are 027, it is important to develop more accurate methods to distinguish between these highly virulent strains. Recently, we fully sequenced the genomes of two 027 isolates, an historic strain (CD196, the original strain isolated in Paris in 1985) and a modern strain (R20291, the index 027 strain isolated in the UK in 2006), which revealed some genetic differences between them (Stabler et al., 2009). More recently, Nyč et al. (2011) reported an outbreak of CDI in the Czech Republic in which the strains were PCR ribotype 176 and closely related to 027 strains. In this study, we determined phenotypic differences in 26 presumed 027 strains from the US and the UK, isolated between 1988 and 2008, and re-evaluated their PCR ribotype. We show that the UK and US 027 strains have distinct motility and antibiotic resistance profiles and demonstrate that some strains previously assumed to be 027 are different PCR ribotypes such as 176, 198 and 244.

**METHODS**

The 26 human clinical isolates examined in this study are summarized in Table 1. These include BI-1 to BI-15 (provided by Dale Gerding, Hines VA Hospital, USA) and ten PCR ribotype 027 strains, 027-01 to 027-10 (provided by Derek J. Brown, Glasgow, Scotland). In addition, M120 (provided by Denise Drudy, University College, Dublin) and R20291 (provided by Jon Brazier, Cardiff, Wales) were used as controls. C. difficile was routinely grown on Brazier's CCEY agar (BioConnections) containing 4% egg yolk, C. difficile supplement (BioConnections) and

1% defibrinated horse blood (TCS Biosciences), in brain heart infusion (BHI) broth (Oxoid) supplemented with 2.5% l-cysteine (Sigma Aldrich) and C. difficile supplement (Fluka) and on blood agar (agar base; Oxoid) supplemented with 7% defibrinated horse blood (TCS Biosciences). All cultures were grown from glycerol stocks in an anaerobic atmosphere (10% CO₂, 10% H₂, 80% N₂) at 37°C.

**PCR ribotyping.** PCR ribotyping was performed at least in duplicate. Briefly, bacteria were harvested from 48 h anaerobic cultures on blood agar. Cells were resuspended into a 5% (w/v) solution of Chelx-100 (Bio-Rad) and heated to 100°C for 12 min. The suspension was separated by centrifugation (13,000 g for 12 min) and the supernatant (10 μl) was added to a 100 μl PCR mixture containing 25 μM each primer (P3, 5’-CTGGGGTGAACTCGTAAACAGG-3’; and P5, 5’-GGGCCCTTTGTAGCTTGACC-3’), 2.5 units Qiagen HotStar Taq DNA polymerase per reaction, 0.4 mM dNTPs and 3.75 mM MgCl₂ per reaction. The reaction mixture was subjected to 30 cycles of 94°C for 1 min, 72°C for 1 min, 94°C for 1 min, 55°C for 1 min, 72°C for 5 min. The PCR products were concentrated to 40 μl by heating at 75°C. Electrophoresis was done at 100 mA in 3% pre-cast Bio-Rad TAE buffer. Banding patterns were analysed using GelCompar software (Applied Maths). R20291 was used as a PCR ribotype 027 control.

**Antibiotic susceptibility test.** A range of antibiotics were used to determine the relative susceptibility to clindamycin, erythromycin, chloramphenicol, tetracycline and fluoroquinolones (moxifloxacin, gatifloxacin and levofloxacin). Strain C. difficile R20291 with known MICs (Drudy et al., 2006; Stabler et al., 2009) was used as a control. The interpretation of MIC results was based on the recommendations given by the guidelines of the Clinical and Laboratory Standards Institute (CLSI, 2008) for all antibiotics used in the present study (Table 2).

Antibiotic susceptibility was determined using the Etest method in all the cases, and the broth dilution method was also used to confirm some of the Etest results. In this case antibiotics were supplied by Sigma-Aldrich.

For the Etest method, a bacterial suspension in BHI to approximately OD₆₀₀=0.5 (McFarland standard no. 3) was plated on blood agar and allowed to dry for 15–30 min. Etest strips (AB Biodisk) were placed onto agar surfaces. Agar plates were incubated anaerobically at 37°C for a further 24 h, and MICs were determined following the manufacturer’s instructions. These were performed in triplicate and R20291 was used as a control (Stabler et al., 2009).

**RESULTS**

**PCR ribotyping**

The strains examined in this study are summarized in Table 1. The 16 US isolates were from multiple States between 1988 and 2004 and pre-date the UK strains, which include the UK index strain R20291 isolated in England in 2006 and 10 strains isolated from different regions in Scotland between 2007 and 2008.

Twenty-three of the 26 isolates were confirmed as PCR ribotype 027. The other three strains were different PCR ribotypes: BI-6 was PCR ribotype 176, BI-11 was PCR ribotype 198 and BI-14 was PCR ribotype 244 (Table 1). The PCR ribotype banding profile of 027 strains consisted of seven distinct bands (Fig. 1a, b). Interestingly, the PCR ribotype 198 (BI-11) and PCR ribotype 176 (BI-6) patterns showed a high level of similarity to the PCR ribotype 027 pattern, differing by just a single band. However, strain BI-14 (PCR ribotype 244) differed by the absence of a band.
and the addition of a different band (Fig. 1a, b). R20291 was used as a control for the 027 PCR ribotype.

**Antibiotic resistance**

Antibiotic susceptibility was tested for all isolates (Fig. 2). The majority of PCR ribotype 027 strains exhibited either intermediate resistance (8/26 strains) (4.5–6 µg ml⁻¹) to clindamycin as well as full resistance to erythromycin (18/26 strains) (MIC ≥128 µg ml⁻¹). The only isolates susceptible to both clindamycin and erythromycin were BI-5 (MIC=2 and 1.75 µg ml⁻¹, respectively) and BI-14 (MIC=2 and 1.5 µg ml⁻¹, respectively). All UK strains and some US strains were highly resistant to fluoroquinolones (20/26 strains) (MIC ≥32 µg ml⁻¹). However, some US strains were fluoroquinolone-susceptible to moxifloxacin (7/26 strains) (MIC=1 µg ml⁻¹), intermediately resistant to levofloxacin (5/26 strains) (MIC=4 µg ml⁻¹) and gatifloxacin-susceptible and/or intermediately resistant (3/26 and 4/26 strains, respectively) (Fig. 2).

BI-1 to BI-5 strains, isolated prior to 2003, showed either intermediate resistance (MIC=16 µg ml⁻¹) or were fully resistant (MIC ≥128 µg ml⁻¹) to chloramphenicol, whereas the other strains were susceptible to this antibiotic in most cases (18/26 strains) (MIC=5–12 µg ml⁻¹). Only BI-7, BI-6p and BI-6p2 were resistant (MIC 18–24 µg ml⁻¹) (Fig. 2). All the strains tested were susceptible to tetracycline (MIC <0.7 µg ml⁻¹). R20291 was used as a control for antibiotic resistance.

**Motility**

There was clear and reproducible evidence of motility among 027 isolates (Fig. 3). US strains (16/26 strains) were motile (stalactite length range: 1.6–1.8 cm) whereas UK strains (10/26 strains) were highly motile (stalactite length range: 2.4–3 cm) (P<0.05) (Fig. 3). The M120 strain is a non-motile negative control (0.7 cm) and R20291 is a highly motile 027 strain positive control (3 cm) (Fig. 3).

**Autoagglutination**

Autoagglutination is often used to demonstrate charge differences on bacterial cells that can be affected by the presence of flagella and how they are modified (Howard et al., 2009). The percentage of autoagglutination was tested for all the isolates. We found a very heterogeneous representation of the autoagglutination phenotype among the strains (Fig. 4).

**DISCUSSION**

Rates and severity of CDI have increased alarmingly in recent years and are in part attributable to the emergence and spread of the 027 clonal lineage (Goorhuis et al., 2007; Hubert et al., 2007; Loo et al., 2005; Mooney, 2007). The 26
presumed PCR ribotype 027 strains investigated in this study were isolated throughout the UK and the US over a 20-year period. The early strains (1988–2004) were from different States in the US and the later strains (2006–2008) were from the UK (Table 1), which presumably emerged from North America. Interestingly, these isolates are

**Fig. 2.** Antibiotic resistance heat map. All 26 strains were tested for their susceptibility to clindamycin, erythromycin, chloramphenicol, tetracycline and fluoroquinolones (levofloxacin, gatifloxacin, moxifloxacin). Black represents resistant, grey represents intermediately resistant and white represents susceptible.

**Fig. 3.** Relative motility assays for *C. difficile* strains. Strains were inoculated into 0.05 % BHI agar and incubated for 24 h in an anaerobic chamber. Motility is visualized as stalactite projections. M120 and R20291 are negative and positive controls, respectively. Bar, 1.2 cm.
C. difficile 027 between PCR ribotype 176 and presumed PCR ribotype BI-6 (PCR ribotype 176) was high. Slight band differences in the ribotype banding pattern for BI-11 (PCR ribotype 198) and BI-6 (PCR ribotype 176). However, the similarity of the PCR bands compared to PCR ribotype 027, being assigned as 54.

Journal of Medical Microbiology (Stabler et al., 2006). In our study, BI-14 had two different bands compared to PCR ribotype 027, being assigned as PCR ribotype 244. However, the similarity of the PCR ribotype banding pattern for BI-11 (PCR ribotype 198) and BI-6 (PCR ribotype 176) was high. Slight band differences between PCR ribotype 176 and presumed PCR ribotype 027. C. difficile isolates have also been observed in Austria (A. Indra, personal communication in 2010) and more recently in the Czech Republic and Poland (Nyč et al., 2011). Despite being different ribotypes, it is clear that the BI-11 (PCR ribotype 198) and BI-6 (PCR ribotype 176) strains are closely related to 027 strains and have previously been placed in the same clade using comparative genome microarray analyses (Stabler et al., 2006). High similarity in PCR ribotyping pattern between 027 and other ribotypes should be monitored, as strains from these ribotypes may be as problematic as the hypervirulent 027 strains.

CDI is frequently linked to treatment with antibiotics which provide an advantage for C. difficile survival (Delaney et al., 2007). In this study, we showed that UK strains were resistant to most of the antibiotics tested. However, US strains showed a variable range of antibiotic resistance depending on the antibiotic. It is a reasonable hypothesis that these changes in antibiotic resistance profiles could be linked to the changes in antibiotic prescription policy over time and in different countries. The most noteworthy is the rise in resistance to fluoroquinolones such as levofloxacin, gatifloxacin and moxifloxacin. With few exceptions, antibiotic resistance in C. difficile is transposon-mediated: erythromycin resistance (ermB) is carried on Tn5398 (Hussain et al., 2005; Sebaihia et al., 2006) or CTnCD11 (He et al., 2010), chloramphenicol resistance (catD) is carried on Tn4453 (Lyra et al., 2004) and tetracycline resistance is carried on Tn5397 (Hussain et al., 2005). Previous studies identified a novel transposon in R20291, CTn-027, encoding a chloramphenicol resistance gene (CDR20291_3461) in some PCR ribotype 027 strains (Stabler et al., 2009). However, all UK strains with the exception of R20291 (used as a control) and some US strains were chloramphenicol-susceptible with some exceptions, indicating that the transmission of this transposon-mediated antibiotic resistance might not be uniform throughout the 027 lineage. On the other hand, tetracycline resistance (tetM), usually carried on Tn5397, was absent in all 26 strains tested. Generally, resistance to macrolides (e.g. erythromycin) and lincosamides (e.g. clindamycin) is mediated via the presence of the ermB gene and it is more common in 027 isolates (Solomon et al., 2011). Although 14 strains were erythromycin- and clindamycin-resistant, TnCD11 carrying ermB was only present in five of the BI isolates (BI-6, BI-7, BI-10, BI-13 and BI-15) analysed by whole genome analysis (He et al., 2010). This suggests an alternative mechanism for ermB resistance in the 027 lineage. The development of antibiotic resistance in modern 027 strains emphasizes the importance of antibiotic susceptibility testing for the emergence of antibiotic resistance.

The flagella-associated genes in strain 630 (PCR ribotype 012) are found in two loci, F1 and F3, separated by an interflagella locus, F2 (Stabler et al., 2009). The level of sequence identity in 027 strains compared to the 630 strain for the F1 and F3 region was high, but there were significant differences in the F2 region (Stabler et al., 2009). This may provide a genetic basis for the motility differences among 027 isolates used in this study, but to date available genetic information on the strains in this study cannot explain the difference in motility between the 027 strains. Modifications in motility
and antibiotic resistance between the 027 strains may reflect a genetic change with respect to the flagella and glycosylation loci as well as the loss and gain of transposons and the accumulation of mutations over time. Such changes could be beneficial for invasion, adhesion, access to nutrients and general survival and transmissibility of C. difficile.

Understanding the evolution of clones such as the PCR ribotype 027 will be important in predicting the early emergence (or disappearance) of highly virulent C. difficile strains and represents a current public health imperative. In this study, phenotypic differences between the 26 UK and US strains suggest that the PCR ribotype 027 is genetically variable. It appears that the 176 and 198 ribotypes have evolved recently from the 027 lineage. Thus there should be a heightened awareness that the recently identified PCR ribotypes 176 and 198 may be as problematic as the 027 strains.

ACKNOWLEDGEMENTS

We acknowledge the Wellcome Trust for funding this research. M.D.C. and E.V. acknowledge the Health Protection Agency Collaborating Centre at UCLH and the Fundación Alfonso Martínez Escudero, respectively, for funding. We thank Derek Brown, Dale Gerdning, Jon Brazier and Denise Drudy for provision of C. difficile strains.
