Postoperative endophthalmitis

Careful preparation of the patient prior to performing an intraocular procedure is vitally important to reduce the risk of endophthalmitis.1 The patient should have 5% povidone iodine instilled into the conjunctival sac and the eye should be carefully draped to isolate the surgical field from the eyelids and the lashes.1,5 The eyelashes need not be cut as cutting the lashes does not reduce periocular bacterial flora and does not reduce the risk of endophthalmitis.5 The surgeon should wash his or her hands effectively and wear sterile gown and gloves.1 At the conclusion of cataract surgery, intracameral cefuroxime, if available, should be given to reduce the risk of endophthalmitis.6

The development of a red eye, pain and blurred vision in the days or weeks following an intraocular procedure should be considered as a case of endophthalmitis until proven otherwise. If intraocular inflammation is discovered, particularly if there is a hypopyon, treatment for endophthalmitis should be initiated without delay.7

NOTE: Do not try to treat with a course of corticosteroids first – this will delay treatment and may result in losing the eye.

An endophthalmitis kit should be accessible in every practice where postoperative patients are seen and is invaluable to allow prompt diagnosis and treatment (see panel below). A vitreous biopsy/tap through the pars plana should be performed immediately for gram stain and culture. If the patient has perception of light only, a vitrectomy has been shown to be more beneficial than a vitreous tap.6 However, if a delay is likely before a vitrectomy can be performed, it is advisable to perform a vitreous tap and inject intravitreal antibiotics for more rapid treatment.

Intravitreal antibiotics (vancomycin and ceftazidime or amikacin and ceftazidime) should be given immediately, using separate syringes and needles for each drug (see panel for instructions to make up the required concentrations of each antibiotic). The use of intravitreal dexamethasone (a steroid) is controversial.

Consider adjunctive systemic therapy – with the same antibiotics as those used intravitreally – for 48 hours to maintain higher levels within the posterior segment of the eye. If systemic antibiotics are not available, topical antibiotics are better than nothing. Careful monitoring of the patient is important. The response to treatment and the results of gram stain and culture should determine whether further intravitreal antibiotic therapy is required.

### Contents of the Endophthalmitis Kit or Pack

**Equipment for preparation of patient**
- **Tetracaine (anaesthetic) drops**
- **Povidone iodine**
- **Drape**
- **Speculum**
- **Equipment for sub-Tenon’s anaesthetic injection**
  - 10 ml 2% lidocaine
  - 10 ml syringe
  - Sub-Tenon’s cannula
  - Westcott scissors
- **Equipment for vitreous biopsy/tap**
  - 23G or 25G needle
  - 5 ml syringe
  - Calipers

**Equipment for preparation of antibiotic injections**
- **1 vial of 500 mg vancomycin or 1 vial of 500 mg (250 mg/ml) amikacin**
- **1 vial of 500 mg ceftazidime**
- **3 x 10 ml sodium chloride 0.9% injection (saline)**

**Vancomycin 1 mg/0.1 ml**
- Reconstitute 500 mg vial with 10 ml saline
- Withdraw all 10 ml into 10 ml syringe
- Inject 2 ml of this solution back into vial
- Add 8 ml saline into vial to make up to 10 ml (10 ml/ml)
- Use 1 ml syringe to draw 0.1 ml of this solution (1 mg/0.1 ml)

**Amikacin 400 µg/0.1 ml**
- Use 10 ml syringe to withdraw 1.6 ml of amikacin (250 mg/ml)
- Make up to 10 ml in the syringe with saline
- Discard 9 ml from syringe and make the remaining 1 ml up to 10 ml (in the syringe) with more saline
- Transfer the solution into a sterile galley pot and use 1 ml syringe to draw 0.1 ml of this solution (400 µg/0.1 ml)

**Ceftazidime 2 mg/0.1 ml**
- Reconstitute 500 mg vial with 10 ml saline
- Withdraw all 10 ml into 10 ml syringe
- Inject 2 ml of this solution back into vial
- Add 3 ml saline into vial to make up to 5 ml (20 mg/ml)
- Use 1 ml syringe to draw 0.1 ml of this solution (2 mg/0.1 ml)
Acute endophthalmitis: prophylaxis, clinical diagnosis and treatment

Risk factors
• Avoid surgery on patients with any known eye infections, e.g. blepharitis or conjunctivitis, or who have a lacrimal duct obstruction.
• Note that patients with an ocular prosthesis in the fellow orbit, or who wear contact lenses, are at risk of infection.

Prophylaxis
• Povidone iodine 5%: cornea and conjunctival sac.
• Povidone iodine 10%: periorbital area; wait a minimum of 3 minutes before incision.

In particular reference to cataract surgery:
• Perform safe surgery (watertight incisions, manage complications effectively).
• Avoid silicone intra-ocular lenses (IOLs).
• Give intracameral injection of 1 mg cefuroxime in 0.1 ml saline (0.9%) at end of surgery.

Prevent
Risk factors
• Avoid surgery on patients with any known eye infections, e.g. blepharitis or conjunctivitis, or who have a lacrimal duct obstruction.
• Note that patients with an ocular prosthesis in the fellow orbit, or who wear contact lenses, are at risk of infection.

Prophylaxis
• Povidone iodine 5%: cornea and conjunctival sac.
• Povidone iodine 10%: periorbital area; wait a minimum of 3 minutes before incision.

In particular reference to cataract surgery:
• Perform safe surgery (watertight incisions, manage complications effectively).
• Avoid silicone intra-ocular lenses (IOLs).
• Give intracameral injection of 1 mg cefuroxime in 0.1 ml saline (0.9%) at end of surgery.

Recognise

1. Suspect endophthalmitis if any of the following symptoms or clinical signs are present, particularly if there is a previous history of infection, intravitreal injection or penetrating trauma.
   • Blurred vision
   • Pain
   • Red eye
   • Hypopyon

2. Perform B-scan ultrasonography (if available) to check for vitritis or retinal detachment.
3. Do not delay diagnosis by first giving a trial of corticosteroid drops!

Respond

Within 1 hour
Perform an intravitreal tap/vitrectomy through the pars plana. Collect samples of vitreous for Gram stain and culture. A vitrectomy may be indicated if the patient has perception of light only.6

TECHNIQUE
How to do an intravitreal tap
• Use aseptic technique with drape
• Instil topical antibiotics and povidone iodine 5%.
• Administer subconjunctival or sub-Tenon’s anaesthetic.
• Insert the needle (23 or 25 G) 4 mm (phakic eyes) or 3.5 mm (pseudophakic/aphakic eyes) behind the limbus into the middle of the vitreous cavity, pointing at the optic disc (approx 7–8 mm deep) and aim to aspirate 0.3–0.5 ml of vitreous fluid.

Immediately following the intravitreal tap, inject antibiotics into the vitreous.
1st choice:
• vancomycin 1 mg in 0.1 ml and
• ceftazidime 2 mg in 0.1 ml
OR 2nd choice:
• amikacin 400 µg in 0.1 ml and
• ceftazidime 2 mg in 0.1 ml

Note: Use a new syringe and a new 30 G needle for each drug. Do not mix drugs together in the same syringe.

Following the injections of intravitreal antibiotics, inject dexamethasone (preservative free) 400 µg in 0.1 ml into the vitreous using a different syringe and 30 G needle. (The use of steroids remains controversial but is recommended by the European Society of Cataract and Refractive Surgeons.) Consider adjunctive systemic therapy with the same antibiotics as those used intravitreally for 48 hours to maintain higher levels within the posterior segment of the eye.
