Text S2. Calculation of incidence rate ratios and 95% confidence intervals

An effect estimate and 95% confidence interval was not reported in this study. However, the data necessary to calculate a rate ratio has been provided in the supplementary appendix. First, we must calculate the point estimate:

\[
\hat{IR} = \frac{A_1/T_1}{A_0/T_0}
\]

A1 = 17 = tuberculosis cases in immediate ART arm
T1 = 1661.9 = person-years at risk of a clinical event in immediate ART arm
A0 = 33 = tuberculosis cases in deferred ART arm
T0 = 1641.8 = person-time at risk of a clinical event in deferred ART arm

\[
IR = \frac{17/1661.9}{33/1641.8} = 0.5089
\]

Next, we must calculate the standard deviation of the log rate ratio:

\[
SD[\ln(\hat{IR})] = \left( \frac{1}{A_1} + \frac{1}{A_0} \right)^{1/2}
\]

\[
SD[\ln(IR)] = (1/17 + 1/33)^{0.5} = 0.2985
\]

Finally, we can calculate the lower and upper limits of the rate ratio:

\[
IR, \hat{IR} = \exp[\ln(\hat{IR}) \pm Z_{\alpha/2}SD[\ln(\hat{IR})]] = \exp[\ln(0.5089) \pm 1.96(0.2985)] = 0.2835, 0.9136
\]

Therefore the rate ratio and its 95% confidence interval is: 0.51 (0.28 to 0.91).

An effect estimate and 95% confidence interval was not reported in participants with baseline CD4 counts < 200 cells/µL. However, the data necessary to calculate a rate ratio has been provided. In order to calculate the tuberculosis rate ratio for people with CD4 counts < 200 cells/µL we must use the incidence rates and their 95% confidence intervals.

The incidence rate in people who started ART with baseline CD4 counts < 200 cells/µL was 0.60 cases / 100 person-years of observation (95% CI, 0.15 to 2.37). Given

\[
\hat{SD}[\ln(\hat{IR})] = \frac{1}{A^{1/2}}
\]

we can solve for the \((1/A^{0.5})\), i.e. the standard deviation of the log incidence rate, using the lower 95% confidence interval:

\[
\ln(95\% \text{ IR Lower Limit, LL}) = \ln(\text{IR}) - Z_y \ \text{SD}[\ln(\text{IR})]
\]

\[
(\ln(\text{LL}) - \ln(\text{IR})) / -Z_y = \text{SD}[\ln(\text{IR})]
\]

\[
\text{SD}[\ln(\text{IR})] = (\ln(0.15) - \ln(0.60)) / -1.96 = 0.7073
\]

Given SD[ln(IR)] we can now calculate A1, or the number of events in the stratum on ART:

\[
\hat{SD}[\ln(\hat{IR})] = \frac{1}{A^{1/2}}
\]

\[
0.7073 = 1/(A1^{0.5})
\]

\[
1 = 0.7073*(A1^{0.5})
\]

\[
1 / 0.7073 = (A1^{0.5})
\]

\[
1.4138 = (A1^{0.5})
\]

\[
1.9989 = A1
\]

A1~2 cases of tuberculosis
The incidence rate in people off ART with baseline CD4 counts < 200 cells/µL was 5.47 cases / 100 person-years of observation (95% CI, 2.73 to 10.94). Given

$$\hat{SD}[\ln(\hat{IR})] = \frac{1}{A^{1/2}}$$

we can solve for the \((1/A^{0.5})\), i.e. the standard deviation of the log incidence rate, using the lower 95% confidence interval:

$$\ln(95\%\ IR\ Lower\ Limit, I.L.) = \ln(\hat{IR}) - Z_y\ SD[\ln(\hat{IR})]$$

\((\ln(LL) - \ln(\hat{IR})) / -Z_y = SD[\ln(\hat{IR})]\)

$$SD[\ln(\hat{IR})] = (\ln(2.73) - \ln(5.47)) / -1.96 = 0.3546$$

Given SD[ln(IR)] we can now calculate \(A_0\), or the number of events in the stratum off ART:

$$0.3546 = 1/(A_0^{0.5})$$

$$1 = 0.3546(A_0^{0.5})$$

$$1 / 0.3546 = (A_0^{0.5})$$

$$2.8202 = (A_0^{0.5})$$

$$7.9537 = A_0$$

\(A_0 \sim 8\) cases of tuberculosis

Since we have calculated the number of cases in both study arms, we can now calculate the rate ratio and its 95% confidence interval. First, we must calculate the point estimate:

$$\hat{IR} = \frac{A_1/T_1}{A_0/T_0}$$

$$IR = (0.60/100) / (5.47/100) = 0.1097$$

Next we must calculate the standard deviation of the log rate ratio:

$$\hat{SD}[\ln(\hat{IR})] = \left(\frac{1}{A_1} + \frac{1}{A_0}\right)^{1/2}$$

$$SD[\ln(\hat{IR})] = (1/2 + 1/8)^{0.5} = 0.7912$$

Finally, we can calculate the 95% limits of the rate ratio:

$$\hat{IR}, \hat{IR} = \exp[\ln(\hat{IR}) \pm Z_y\ SD[\ln(\hat{IR})]]$$

$$=\exp[\ln(0.1097) \pm 1.96(0.7912)] = 0.0233, 0.5172$$

Therefore the rate ratio and its 95% confidence interval is: 0.11 (0.02 to 0.52).
