ABSTRACT

Background

There is inconclusive evidence from observational studies to suggest that people who eat a diet rich in antioxidant vitamins (carotenoids, vitamins C, and E) or minerals (selenium and zinc) may be less likely to develop age-related macular degeneration (AMD).

Objectives

To determine whether or not taking antioxidant vitamin or mineral supplements, or both, prevent the development of AMD.

Search methods

We searched the Cochrane Central Register of Controlled Trials (CENTRAL) (which contains the Cochrane Eyes and Vision Trials Register) (2017, Issue 2), MEDLINE Ovid (1946 to 29 March 2017), Embase Ovid (1947 to 29 March 2017), AMED (Allied and Complementary Medicine Database) (1985 to 29 March 2017), OpenGrey (System for Information on Grey Literature in Europe) (www.opengrey.eu/); searched 29 March 2017, the ISRCTN registry (www.isrctn.com/editAdvancedSearch); searched 29 March 2017, ClinicalTrials.gov (www.clinicaltrials.gov); searched 29 March 2017 and the WHO International Clinical Trials Registry Platform (ICTRP) (www.who.int/ictrp/search/en); searched 29 March 2017. We did not use any date or language restrictions in the electronic searches for trials.

Selection criteria

We included all randomised controlled trials (RCTs) comparing an antioxidant vitamin or mineral supplement (alone or in combination) to control.

Data collection and analysis

Both review authors independently assessed risk of bias in the included studies and extracted data. One author entered data into RevMan 5; the other author checked the data entry. We pooled data using a fixed-effect model. We graded the certainty of the evidence using GRADE.
**Main results**

We included a total of five RCTs in this review with data available for 76,756 people. The trials were conducted in Australia, Finland, and the USA, and investigated vitamin C, vitamin E, beta-carotene, and multivitamin supplements. All trials were judged to be at low risk of bias.

Four studies reported the comparison of vitamin E with placebo. Average treatment and follow-up duration ranged from 4 to 10 years. Data were available for a total of 55,614 participants. There was evidence that vitamin E supplements do not prevent the development of any AMD (risk ratio (RR) 0.97, 95% confidence interval (CI) 0.90 to 1.06; high-certainty evidence), and may slightly increase the risk of late AMD (RR 1.22, 95% CI 0.89 to 1.67; moderate-certainty evidence) compared with placebo. Only one study (941 participants) reported data separately for neovascular AMD and geographic atrophy. There were 10 cases of neovascular AMD (RR 3.62, 95% CI 0.77 to 16.95; very low-certainty evidence), and four cases of geographic atrophy (RR 2.71, 95% CI 0.28 to 26.0; very low-certainty evidence). Two trials reported similar numbers of adverse events in the vitamin E and placebo groups. Another trial reported excess of haemorrhagic strokes in the vitamin E group (39 versus 23 events, hazard ratio 1.74, 95% CI 1.04 to 2.91, low-certainty evidence).

Two studies reported the comparison of beta-carotene with placebo. These studies took place in Finland and the USA. Both trials enrolled men only. Average treatment and follow-up duration was 6 years and 12 years. Data were available for a total of 22,083 participants. There was evidence that beta-carotene supplements did not prevent any AMD (RR 1.00, 95% CI 0.88 to 1.14; high-certainty evidence) nor have an important effect on late AMD (RR 0.90, 95% CI 0.65 to 1.24; moderate-certainty evidence). Only one study (941 participants) reported data separately for neovascular AMD and geographic atrophy. There were 10 cases of neovascular AMD (RR 0.61, 95% CI 0.17 to 2.15; very low-certainty evidence) and 4 cases of geographic atrophy (RR 0.31, 95% CI 0.03 to 2.93; very low-certainty evidence). Beta-carotene was associated with increased risk of lung cancer in people who smoked.

One study reported the comparison of vitamin C with placebo, and multivitamin (Centrum Silver) versus placebo. This was a study in men in the USA with average treatment duration and follow-up of 8 years for vitamin C and 11 years for multivitamin. Data were available for a total of 14,236 participants. AMD was assessed by self-report followed by medical record review. There was evidence that vitamin C supplementation did not prevent any AMD (RR 0.96, 95% CI 0.79 to 1.18; high-certainty evidence) or late AMD (RR 0.94, 0.61 to 1.46; moderate-certainty evidence). There was a slight increased risk of any AMD (RR 1.21, 95% CI 1.02 to 1.43; moderate-certainty evidence) and late AMD (RR 1.22, 95% CI 0.88 to 1.69; moderate-certainty evidence) in the multivitamin group. Neovascular AMD and geographic atrophy were not reported separately. Adverse effects were not reported but there was possible increased risk of skin rashes in the multivitamin group.

Adverse effects were not consistently reported in these eye studies, but there is evidence from other large studies that beta-carotene increases the risk of lung cancer in people who smoke or who have been exposed to asbestos.

None of the studies reported quality of life or resource use and costs.

**Authors’ conclusions**

Taking vitamin E or beta-carotene supplements will not prevent or delay the onset of AMD. The same probably applies to vitamin C and the multivitamin (Centrum Silver) investigated in the one trial reported to date. There is no evidence with respect to other antioxidant supplements, such as lutein and zeaxanthin. Although generally regarded as safe, vitamin supplements may have harmful effects, and clear evidence of benefit is needed before they can be recommended. People with AMD should see the related Cochrane Review on antioxidant vitamin and mineral supplements for slowing the progression of AMD, written by the same review team.

**Plain Language Summary**

Antioxidant vitamin and mineral supplements to prevent the development of age-related macular degeneration (AMD)

**What is the aim of this review?**

The aim of this Cochrane Review was to find out whether taking antioxidant vitamin and mineral supplements prevents the development of AMD. Cochrane researchers collected and analysed all relevant studies to answer this question and found five studies.

**Key messages**
Taking vitamin E or beta-carotene supplements will not prevent the onset of AMD in people who do not have signs of the condition. The same probably applies to vitamin C and multivitamin tablets. There is no evidence for other supplements, such as lutein and zeaxanthin.

What was studied in the review?

AMD is a condition of the central area (macula) of the back of the eye (retina). The macula degenerates with age. In some people, this deterioration happens more quickly, and is associated with a particular appearance at the back of the eye. In its earliest stage (early AMD), yellow spots (drusen) can be seen under the retina by an eye health professional on examining the eye. The affected person will probably be unaware that they have a problem. As AMD progresses, it can lead to the loss of the cells in the back of the eye, which are needed for vision. This is known as geographic atrophy. Sometimes, new (harmful) blood vessels grow in the macula. These new blood vessels may bleed and cause scarring. This is known as neovascular or wet AMD. Any damage to the macula can affect vision, particularly central vision. Neovascular AMD and geographic atrophy are known as late AMD.

It is possible that antioxidant vitamins may help to protect the macula against this deterioration and loss of vision. Vitamin C, E, beta-carotene, lutein, zeaxanthin, and zinc are examples of antioxidant vitamins commonly found in vitamin supplements.

The Cochrane researchers only looked at the effects of these supplements in healthy people in the general population who did not yet have AMD. There is another Cochrane Review on the effects of these supplements in people who already have AMD.

What are the main results of the review?

The Cochrane researchers found five relevant studies. The studies were large and included a total of 76,756 people. They took place in Australia, Finland, and the USA. The studies compared vitamin C, vitamin E, beta-carotene, and multivitamin supplements with placebo.

The review showed that, compared with taking a placebo:

- Taking vitamin E supplements made little or no difference to the chances of developing AMD (high-certainty evidence).
- Taking vitamin E supplements made little difference, or slightly increased, the chances of developing late AMD (moderate-certainty evidence).
- Taking beta-carotene made little or no difference to the chances of developing any AMD (high-certainty evidence) or late AMD (moderate-certainty evidence).
- Taking vitamin C made little or no difference to the chances of developing any AMD (high-certainty evidence) or late AMD (moderate-certainty evidence).
- Taking multivitamin tablets may slightly increase the chances of developing any AMD or late AMD (moderate-certainty evidence).
- Adverse effects were not consistently reported in these eye studies, but there is evidence from other large studies that beta-carotene increases the risk of lung cancer in people who smoke, or who have been exposed to asbestos.

None of the studies reported quality of life or resource use and costs.

How up-to-date is this review?

The Cochrane researchers searched for studies that had been published up to 29 March 2017.
## Summary of Findings for the Main Comparison

### Vitamin E versus Placebo

**Patient or population:** general population  
**Setting:** community  
**Intervention:** vitamin E  
**Comparison:** placebo

### Adverse effects (AE)

| Resource use and costs | - | - | - | - | Not reported |

Two trials reported similar numbers of AEs in vitamin E and placebo group. Another trial reported excess of haemorrhagic strokes in vitamin E group (39 vs 23 events, hazard ratio 1.74, 95% CI 1.04 to 2.91).

| \* Dose of vitamin E used in studies were: 50 mg/day, 400 IU/alternate days, 600 IU/alternate days, and 500 IU/day |
| ** The risk in the placebo group is the median risk in the placebo groups in the included studies. The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI). |

CI: Confidence interval; RR: Risk ratio

### GRADE Working Group grades of evidence

| High-certainty: We are very confident that the true effect lies close to that of the estimate of the effect |
| Moderate-certainty: We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different |
| Low-certainty: Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect |
| Very low-certainty: We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect |

1 Downgraded one level for imprecision due to wide confidence intervals i.e. are below 0.8 or above 1.25.
2 Downgraded one level for indirectness (only one trial in male smokers) and downgraded two levels for imprecision as very few cases (10 neovascular AMD, 4 geographic atrophy)
3 Downgraded one level for imprecision due to wide confidence intervals and lower confidence near 1 and downgraded one level for inconsistency as effect only reported by one trial.
BACKGROUND

Description of the condition
Age-related macular degeneration (AMD) is a disease affecting the central area of the retina (macula). In the early stages of the disease, lipid material accumulates in deposits underneath the retinal pigment epithelium. These deposits are known as drusen, and can be seen as pale yellow spots on the retina. The pigment of the retinal pigment epithelium may become disturbed, with areas of hyperpigmentation and hypopigmentation. In the later stages of the disease, the retinal pigment epithelium may atrophy completely. This loss can occur in small focal areas or be widespread (geographic). In some cases, new blood vessels grow under the retinal pigment epithelium, and occasionally, into the subretinal space (exudative or neovascular AMD). Haemorrhage can occur, which often results in increased scarring of the retina.

The early stages of the disease are, in general, asymptomatic. In the later stages, there may be considerable distortion within the central visual field, leading to a complete loss of central visual function. Population-based studies suggest that, in people 65 years and older, approximately 5% have advanced AMD (Owen 2012). It is the most common cause of blindness and visual impairment in industrialised countries. In the UK, for example, over 30,000 people are registered as blind or partially sighted annually, half of whom have lost their vision due to macular degeneration (Bunce 2006).

Description of the intervention
Photoreceptors in the retina are subject to oxidative stress throughout life, due to combined exposures to light and oxygen. It has been proposed that antioxidants may prevent cellular damage in the retina by reacting with free radicals produced in the process of light absorption (Christen 1996).

There are a number of non-experimental studies that have examined the possible association between antioxidant micronutrients and AMD, although few studies have examined supplementation specifically (Chong 2007; Evans 2001). Data on vitamin intake in observational studies should be considered cautiously, as people who have a diet rich in antioxidant vitamins and minerals, or who choose to take supplements regularly, are different in many ways from those who do not; these differences may not be adequately controlled by statistical analysis. The results of these observational studies have been inconclusive.

How the intervention might work
The underlying theory is that antioxidant vitamin and mineral supplements will protect the retina against oxidative stress, and that this protection will delay the onset of AMD.

Why it is important to do this review
Antioxidant vitamin and mineral supplements are increasingly being marketed for use in age-related eye disease, including AMD. The aim of this review was to examine the evidence on whether taking vitamin or mineral supplements prevents the development of AMD. See also the related Cochrane Review on antioxidant vitamin and mineral supplements for slowing the progression of AMD, which considered whether supplementation for people with AMD slowed down the progression of the disease (Evans 2017).

OBJECTIVES
To determine whether or not taking antioxidant vitamin or mineral supplements, or both, prevent the development of AMD.

METHODS

Criteria for considering studies for this review

Types of studies
We included randomised controlled trials (RCTs) that compared antioxidant vitamin or mineral supplements, (alone or in combination) with control (placebo or no treatment).

Types of participants
Participants in the trials were people in the general population, with or without diseases other than AMD. We excluded trials in which the participants were exclusively people with AMD. These trials were considered in a separate Cochrane Review that examined the effect of supplementation on progression of the disease (Evans 2017).

Types of interventions
We defined antioxidants as any vitamin or mineral that was known to have antioxidant properties in vivo or which was known to be an important component of an antioxidant enzyme present in the retina. We considered the following: vitamin C, vitamin E, carotenoids (including the macula pigment carotenoids lutein and zeaxanthin), selenium and zinc.
**Types of outcome measures**

We modified our protocol for the current update (2017) to include outcomes specified by the UK NICE macular degeneration guideline panel (NICE 2016) - see Differences between protocol and review.

We considered the following outcomes:

- **Development of:**
  - any AMD (early or late AMD, or both)
  - late AMD (neovascular AMD or geographic atrophy, or both)
  - neovascular AMD
  - geographic atrophy

- **Quality of life**

- **Resource use and costs**

**Follow-up:**

We considered the maximum follow-up identified in the studies.

**Adverse effects**

We considered any adverse effects reported by the included studies.

**Search methods for identification of studies**

**Electronic searches**

The Cochrane Eyes and Vision Information Specialist conducted systematic searches in the following databases for randomised controlled trials and controlled clinical trials. There were no language or publication year restrictions. The date of the search was 29 March 2017.

- Cochrane Central Register of Controlled Trials (CENTRAL; 2017, Issue 2) (which contains the Cochrane Eyes and Vision Trials Register) in the Cochrane Library (searched 29 March 2017) (Appendix 1);
- MEDLINE Ovid (1946 to 29 March 2017) (Appendix 2);
- Embase Ovid (1980 to 29 March 2017) (Appendix 3);
- AMED (Allied and Complementary Medicine Database) (1985 to 29 March 2017) (Appendix 4);
- OpenGrey (System for Information on Grey Literature in Europe) (www.opengrey.eu; searched 29 March 2017) (Appendix 5);
- ISRCTN registry (www.isrctn.com/editAdvancedSearch; searched 29 March 2017) (Appendix 6);
- US National Institutes of Health Ongoing Trials Register ClinicalTrials.gov (www.clinicaltrials.gov; searched 29 March 2017) (Appendix 7);
- World Health Organization International Clinical Trials Registry Platform (www.who.int/ictrp; searched 29 March 2017) (Appendix 8).

For the 2012 and 2017 updates, we specifically looked for adverse effects, using a simple search aimed to identify systematic reviews of adverse effects of vitamin supplements, see Appendix 9 for search strategy.

**Searching other resources**

We searched the Science Citation Index and the reference lists of reports of trials that were selected for inclusion. We contacted the investigators of included and excluded trials to ask if they knew of any other relevant published or unpublished trials.

**Data collection and analysis**

**Selection of studies**

Our initial searches identified all trials of antioxidant supplements, and therefore, generated many citations. Each review author independently assessed half of the titles and abstracts resulting from the searches, and selected studies according to the definitions in the Criteria for considering studies for this review. To check that we were consistent, we both assessed a subset of 100 records and compared results. We obtained full copies of all reports referring to controlled trials that definitely or potentially met the inclusion criteria. We assessed the full copies and selected studies according to the inclusion criteria. We wrote to authors of trials for which there were no published outcome data on AMD, to ask whether they had collected any data on eye disease outcomes. As none of the trial authors responded positively, i.e. gave us unpublished data on AMD, for further updates of this review we only considered trials with published data on AMD.

In updates to this review, both authors independently went through the titles and abstracts resulting from the searches, and resolved disagreements by discussion.

**Data extraction and management**

We extracted data using methods’ forms developed by Cochrane Eyes and Vision (eyes.cochrane.org/resources-review-authors). We independently extracted data, and resolved disagreements by discussion. One author cut and pasted the data into Review Manager 5 (Review Manager 5 2014), and the other author checked that this had been done correctly.

For the 2017 update, we screened and extracted data using web-based review management software (Covidence 2015).

**Assessment of risk of bias in included studies**

Both authors independently assessed risk of bias using the Cochrane tool for assessing risk of bias, as described in Chapter 8 of the Cochrane Handbook for Systematic Reviews of Interventions.
We resolved disagreements by discussion. The review authors were not masked to any trial details.

**Measures of treatment effect**

Our measure of treatment effect was the risk ratio (RR) for dichotomous outcomes and the mean difference (MD) for continuous outcomes. Currently the review only includes analysis of dichotomous outcomes.

**Unit of analysis issues**

By definition, the interventions were applied to the person, but as most people have two eyes, trials can analyse data from one or both eyes. In all the trials included in this review the unit of analysis was the person and severity was classified for the worse eye.

**Assessment of heterogeneity**

We assessed heterogeneity by visual inspection of the forest plot, the Chi² test for heterogeneity and the I² statistic.

**Data synthesis**

Where appropriate, we pooled data using a fixed-effect model, after testing for heterogeneity between trial results using a standard Chi² test.

**Subgroup analysis and investigation of heterogeneity**

We did not plan any subgroup analyses. Only five trials are included at present, which means that it is not possible to formally investigate heterogeneity.

**Sensitivity analysis**

We had planned to conduct sensitivity analyses to determine the impact of study quality on effect size. Currently there are only high-quality trials included in the review, and therefore, this is not relevant at present.

**Summary of findings’ tables**

We prepared separate ‘Summary of findings’ tables for the different types of vitamin supplement, i.e. vitamin C, vitamin E, beta-carotene, and multivitamin.

We assessed the certainty of the evidence (GRADE) for each outcome using customised software (GRADEpro 2014). JE did the initial assessment, which was checked by JL. We considered risk of bias, inconsistency, indirectness, imprecision, and publication bias when judging the certainty of the evidence (Schünemann 2011). The ‘Summary of findings’ tables include an estimate of the risk of each outcome in the general population. We derived these from the median risk in the placebo group in four of the studies included in the review (ATBC 1998; PHS II 2012; VECAT 2002; WHS 2010). As there was overlap in participants between PHS I 2007 and PHS II 2012, we just used data from PHS II 2012 for this estimate.

**RESULTS**

**Description of studies**

**Results of the search**

The initial searches resulted in 3178 titles and abstracts. Of these, 208 were potentially eligible trials reports. From these reports, we identified seven primary prevention trials of antioxidant vitamin or mineral supplements (ATBC 1994; CARET 1996; De Klerk 1998; LINXIAN 1993; Nambour 1995; PHS I 2007; WHS 2010). Investigators from three trials have confirmed that they did not collect data on AMD (CARET 1996; De Klerk 1998; Nambour 1995). We excluded these trials from the review. We did not receive a response from one trial author; we excluded this trial (LINXIAN 1993). Three trials had published data on AMD outcomes; we included them in this review (ATBC 1994; PHS I 2007; WHS 2010). Search of the National Eye Institute Clinical Research register identified one further ongoing trial that was collecting information on AMD - the Women's Antioxidant Cardiovascular Study (WACS). There are two trials that have recruited participants with and without AMD (AREDS 2001; VECAT 2002). We included VECAT 2002 in this review because 82% of participants did not have signs of AMD. We excluded AREDS 2001 because it did not include AMD outcomes for people without AMD at baseline; it is included in the Cochrane Review examining the effect of supplementation on progression of the disease (Evans 2017).

In our original search strategy, we identified all trials of antioxidant interventions and asked trialists if they had collected data on AMD. We wrote to the authors of 60 trials of antioxidant interventions in people with diseases other than AMD. We received 15 responses, and none had collected any relevant data. We included all 60 trials in the excluded studies section of this review. As this proved to be an inefficient way of identifying relevant trials, we included terms for AMD in subsequent searches. We found 367 reports of trials in May 2002, 343 in May 2005, and 64 reports in January 2006, but we did not identify any further trials that were relevant for this review. The results of the PHS I study were published in 2007.

We repeated the searches in August 2007, at which time we identified a total of 129 reports of studies. The Trial Search Co-ordinator (TSC) scanned the search results and removed 84 references that were not relevant to the scope of the review. We screened the titles...
and abstracts of the remaining 45 references and obtained full-
text copies of four reports to assess for potential inclusion in the
review. We identified one new report from the PHS I 2007 study
to include in the review and excluded the three remaining stud-
ies. For reasons of exclusion, see the 'Characteristics of excluded
studies' table.

An update search was done in January 2012 which yielded 477
titles and abstracts. The TSC scanned the search results and re-
moved 206 references which were not relevant to the scope of the
review. We screened the title and abstracts of the remaining 271
references. We rejected 267 abstracts as not eligible for inclusion
in the review. We obtained full-text copies of four reports for fur-
ther examination. One new report from the WHS 2010 study has
been included in the review and three other studies were excluded.

For reasons of exclusion, see Characteristics of excluded studies.
Update searches run in March 2017 yielded a further 872 records
(Figure 1). After 157 duplicates were removed, the Cochrane In-
formation Specialist (CIS; formerly the Trial Search Co-ordinator)
screened the remaining 715 records and removed 562 references
that were not relevant to the scope of the review. We screened
the remaining 153 references and obtained one full-text report for
further assessment, however, this study did not meet the inclusion
criteria. We checked the status of the ongoing studies published
in the previous version of this review. PHS II 2012 was now com-
pleted and we included it in this update. AREDS2 2008 was also
completed, however, this study did not meet the inclusion criteria;
see Characteristics of excluded studies for details.
Figure 1. Study flow diagram.

4 studies in previous version of the review (searches as of January 2012) → 872 records identified through electronic database searching (January 2012 to March 2017)

715 records after duplicates removed → 715 records screened by the Cochrane Information Specialist (CIS)

153 records screened by the authors → 152 records excluded by the authors as not relevant

1 full-text article assessed for eligibility → 1 full-text article excluded, with reasons

2 ongoing studies (PHS II and AREDS 2) from the previous version of this review have now been completed and have been assessed for potential inclusion

AREDS excluded

PHS II assessed and included in this update

5 studies included in qualitative synthesis

5 studies included in quantitative synthesis (meta-analysis)
Included studies
See the 'Characteristics of included studies' table for more detailed information.

Types of participants
The studies took place in Australia, USA, and Finland. Three studies recruited men only (ATBC 1998; PHS I 2007; PHS II 2012), one study recruited women only (WHS 2010), and one study recruited both men and women (VECAT 2002). There was overlap of the participants in PHS I 2007 and PHS II 2012, as some participants in PHS II 2012 were recruited from PHS I 2007.

People taking part in the trials were identified from the general population. Participants in PHS I 2007 and PHS II 2012 were male physicians, and in WHS 2010 were female health professionals. In ATBC 1998, a random sample of 1035 men aged 65 years or older from the main study were invited to participate, with a response of 91% (941 men). In VECAT 2002, 18% of participants had AMD at baseline.

Types of intervention
In ATBC 1998, the groups received either alpha-tocopherol 50 mg per day alone, beta-carotene 20 mg per day alone, alphatocopherol and beta-carotene, or placebo. All formulations were coloured with quinoline yellow. Treatment duration was five to eight years (median 6.1 years). In VECAT 2002, participants were randomised to vitamin E (500 IU a day) or placebo. Supplementation continued for four years. In PHS I 2007, the groups received aspirin 325 mg every other day, beta-carotene 50 mg every other day, aspirin and beta-carotene, or placebo. Treatment duration averaged 12 years. In PHS II 2012, participants received vitamin C (500 mg daily), vitamin E (400 IU on alternate days), or daily multivitamin (Centrum Silver), or corresponding placebos. A beta-carotene arm was discontinued in 2003, and results not reported. In WHS 2010, participants received vitamin E (600 IU on alternate days) or placebo, and were followed up for 10 years.

Types of outcome measures
In ATBC 1998, three photographs of each eye were taken with a Canon fundus camera at 40- and 60-degree angles on Kodak Ektachrome 100 ASA slide film. These photographs were graded by one observer, masked to the participant's treatment group. The following grades of maculopathy were used: 0 = none; I = dry maculopathy with hard drusen, pigmentary changes, or both; II = soft macular drusen; III = disciform degeneration; IV = geographic atrophy.

In PHS I 2007, PHS II 2012, and WHS 2010, AMD was ascertained by self report: “Have you ever had macular degeneration diagnosed in your right or left eye?”. If the participant answered yes to this question, permission was gained to contact their ophthalmologist or optometrist, and further details were obtained from the medical records.

In VECAT 2002, photographs were taken with a Nidek 3-DX fundus camera on Kodachrome 64 ASA colour film. The photographs were graded at baseline independently by two trained graders. Early AMD (the primary outcome) was defined as soft drusen (distinct or indistinct) or pigmentary changes (hyperpigmentation or hypopigmentation) on photographic grading. On clinical grading, this was large, soft drusen or non-geographical retinal pigment epithelium atrophy. VECAT 2002 used Bailey-Lovie visual acuity charts #4 and #5 (National Vision Research Institute, Australia).

Table 1 shows how the AMD outcome measures in the included studies were mapped onto the pre-specified review outcomes.

Excluded studies
See the 'Characteristics of excluded studies' table for further information.

Risk of bias in included studies
We considered all five trials to be at low risk of bias (Figure 2; Figure 3). See 'Risk of bias' tables for each included study for details of the assessment.
Figure 2. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.
Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Effects of interventions

See: Summary of findings for the main comparison Vitamin E versus placebo; Summary of findings 2 Beta-carotene versus placebo; Summary of findings 3 Vitamin C versus placebo; Summary of findings 4 Multivitamin versus placebo.

See Table 1 for details of how the AMD outcomes reported in the trials map to the review outcomes reported here. None of the studies reported quality of life or resource use and costs. For details of the GRADE assessments, see the 'Summary of findings' tables (Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3; Summary of findings 4).

Vitamin E versus placebo

Summary of findings for the main comparison

Four studies reported this comparison (ATBC 1998; PHS II 2012; VECAT 2002; WHS 2010). These studies took place in Australia (VECAT 2002), Finland (ATBC 1998), and USA (PHS II 2012; WHS 2010). Men (ATBC 1998; PHS II 2012), women (WHS 2010), or both (VECAT 2002) were enrolled. Average treatment and follow-up duration ranged from 4 years (VECAT 2002) to 10 years (WHS 2010). Data were available for a total of 55,614 participants.

The risk ratio for any AMD was 0.97 (95% CI 0.90 to 1.06; high-certainty evidence; Analysis 1.1) and for late AMD was 1.22 (95% CI 0.89 to 1.67; moderate-certainty evidence; Analysis 1.2).

Only one study (941 participants) reported data separately for neovascular AMD and geographic atrophy (ATBC 1998). There were 10 cases of neovascular AMD (RR 3.62, 95% CI 0.77 to 16.95; very low-certainty evidence) and four cases of geographic atrophy (RR 2.71, 95% CI 0.28 to 26.0; very low-certainty evidence).

Beta-carotene versus placebo

Summary of findings 2

Two studies reported this comparison (ATBC 1998; PHS I 2007). These studies took place in Finland (ATBC 1998), and USA (PHS I 2007). Both trials enrolled men only. Average treatment and follow-up duration was six years (ATBC 1998), and 12 years (PHS I 2007). Data were available for a total of 22,083 participants.

The risk ratio for any AMD was 1.00 (95% CI 0.88 to 1.14; high-certainty evidence; Analysis 2.1), and 0.90 (95% CI 0.65 to 1.24; moderate-certainty evidence; Analysis 2.2) for late AMD.

Only one study (941 participants) reported data separately for neovascular AMD and geographic atrophy (ATBC 1998). There were 10 cases of neovascular AMD (RR 0.61, 95% CI 0.17 to 2.15; very low-certainty evidence) and four cases of geographic atrophy (RR 0.31 95% CI 0.03 to 2.93; very low-certainty evidence).

Vitamin C versus placebo

Summary of findings 3

One study reported this comparison (PHS II 2012). PHS II 2012 was a study on men in the USA, with average treatment duration and follow-up of eight years. Data were available for a total of 14,236 participants.

The risk ratio (RR) for any AMD was 0.96 (95% CI 0.79 to 1.18; high-certainty evidence) and for late AMD was 0.94 (0.61 to 1.46; moderate-certainty evidence; Analysis 3.1). The authors also reported similar hazard ratios (HR), which were adjusted for the other treatment assignments (vitamin E, beta-carotene, and multivitamin treatment assignments). These HRs were 0.96 (0.78 to 1.18) for any AMD, and 0.94 (0.60 to 1.4) for late AMD. Neovascular AMD and geographic atrophy were not reported separately.

Multivitamin versus placebo

Summary of findings 4

One study reported this comparison (PHS II 2012). This study took place in the USA; they enrolled men only and followed them up for an average of 11 years. Data were available for a total of 14,233 participants.

The risk ratio for any AMD was 1.21 (95% CI 1.02 to 1.43; moderate-certainty evidence), and 1.22 (95% CI 0.88 to 1.69; moderate certainty evidence; Analysis 4.1) for late AMD. The authors also reported HRs, which were adjusted for the cohort (PHS I and PHS II) and other treatment assignments (vitamin C, vitamin E, and beta-carotene). These HRs were 1.22 (95% CI 1.03 to 1.44) for any AMD and 1.22 (95% CI 0.88 to 1.70) for late AMD. Neovascular AMD and geographic atrophy were not reported separately.

Adverse effects

Included studies

In general, the publications that reported eye outcomes did not report adverse effects. We also looked at the reports of the main study results for those trials where eye outcomes were collected as part of a larger trial. In VECAT 2002, it was noted that no serious adverse effects were seen. Similar numbers of people in the vitamin E and placebo groups withdrew due to adverse effects (four versus seven), reported any adverse effect (91 versus 83), or ocular adverse effect (105 versus 90).
The main ATBC 1998 trial found an increased risk of lung cancer associated with beta-carotene supplementation (ATBC 1994), a finding that was repeated in the large CARET trial (Ommen 1996). Beta-carotene supplementation is contra-indicated in people who smoke or have been exposed to asbestos.

In the main WHS 2010 trial, “We examined whether vitamin E increased adverse effects due to bleeding (gastrointestinal bleeding, hematuria, easy bruising, epistaxis) because of the potential for vitamin E to inhibit platelet function, gastrointestinal symptoms (gastric upset, nausea, diarrhea, constipation), or fatigue. There were no differences between reported adverse effects for any of these variables among women in the two groups, apart from a small, but significant, increase in the risk of epistaxis (RR 1.06, 95% CI 1.01 to 1.11; P = 0.02)” (Lee 2005).

In PHS II 2012, “An excess number of hemorrhagic strokes was observed among those assigned to vitamin E compared with placebo (39 versus 23 events; HR 1.74, 95% CI 1.04 to 2.91)” (Gaziano 2009), and “We observed no significant differences in adverse effects, including hematuria, easy bruising, and epistaxis, for active vitamin E or C compared with placebo” (Sesso 2008). For multivitamins “...no significant effects on gastrointestinal tract symptoms (peptic ulcer, constipation, diarrhea, gastritis, and nausea), fatigue, drowsiness, skin discoloration, and migraine (all P > 0.05). Those taking the active versus placebo multivitamin were more likely to have skin rashes (2111 and 1973 men in corresponding active and placebo multivitamin groups; HR 1.08, 95% CI 1.01 to 1.15; P = 0.016). In addition, there were inconsistent findings for daily multivitamin use on minor bleeding, with a reduction in hematuria (998 and 1105 men in corresponding active and placebo multivitamin groups; HR 0.89, 95% CI 0.81 to 0.97; P = 0.006), an increase in epistaxis (1216 and 1106 men in corresponding active and placebo multivitamin groups; HR 1.11, 95% CI 1.02 to 1.20; P = 0.016), and no effect on easy bruising/other bleeding (1927 and 1902 men in corresponding active and placebo multivitamin groups; HR 1.02, 95% CI 0.96 to 1.08; P = 0.59)” (Gaziano 2012).

Other systematic reviews

Reviews identified by the search in Appendix 9, for example, Huang 2006, did not identify any consistent adverse effects of mineral and vitamin supplements, but only included nine RCTs in their review. A subsequent Cochrane Review including 78 trials with 296,707 participants concluded “We found no evidence to support antioxidant supplements for primary or secondary prevention. Beta-carotene and vitamin E seem to increase mortality, and so may higher doses of vitamin A” (Bjelakovic 2012).

Summary of main results
This review provides evidence that people who take vitamin E or beta-carotene supplements do not reduce their risk of developing age-related macular degeneration (AMD; Summary of findings for the main comparison; Summary of findings 2). There is more limited evidence on vitamin C (Summary of findings 3), and one multivitamin (Centrum Silver, Summary of findings 4), but at present, nothing to suggest that these supplements prevent AMD.

Overall completeness and applicability of evidence
This review includes five large, high-quality studies that randomised over 75,000 members of the population to antioxidant supplementation or placebo. Duration of supplementation in these studies ranged from 4 to 12 years. In ATBC 1994, there was no association with the treatment group and development of early stages of the disease. If anything, there was a tendency for more cases to be present in the treatment rather than the placebo group. This was not statistically significant. One drawback of adding a maculopathy study to a trial of primary prevention is that we have no information on maculopathy status before supplementation. Therefore, we have to assume that (1) maculopathy was equally distributed across study groups at the start of the study, and (2) most observed events occurred during the study period. It is likely that this was true for a reasonable proportion of the events, as the maculopathy study began eight years after recruitment for the main trial, and randomisation should have ensured equal distribution of maculopathy between the two groups.
Supplementation in this study began at age 50 to 69 years and lasted for five to eight years. Currently, we do not know at what age antioxidant protection may be important. It may be that this was too late or too short a period of supplementation to show an effect. This study was conducted in Finnish male smokers, and we have to be cautious in extrapolating the findings to other geographical areas, to people in other age groups, to women, and to non-smokers. However, the incidence of AMD, particularly neovascular disease, is likely to be higher in smokers, which means that they provide a good population to demonstrate any potential protective effects of antioxidant supplementation (Klein 1993). Similarly, the results of VECAT 2002 do not provide evidence of a benefit of supplementation in people with no, mild, or borderline AMD, although again, these studies have been underpowered to examine late-stage disease.
In the PHS I 2007, over 20,000 physicians received supplementation with beta-carotene over 12 years. There was little evidence of any benefit of beta-carotene supplementation. They used medical record review to ascertain AMD, and therefore may have been less accurate. However, there was no reason to suppose that the ascertainment would have been different in the treatment and control groups. The same method of ascertainment was used in PHS II 2012 and WHS 2010.
This review does not provide evidence on the effects of other antioxidant vitamin and mineral supplements on the development of AMD; in particular, it does not provide evidence on the effects of commonly marketed vitamin combinations. There are additional ongoing studies, including the Women's antioxidant cardiovascular study (WACS), and SELECT study that are collecting data on AMD outcomes. Although generally regarded as safe, antioxidant supplements may have harmful effects. Our review does not provide a systematic review of all possible adverse effects of supplements, but does highlight the fact that beta-carotene increases the risk of lung cancer and overall, there was some evidence of a small, increased risk of mortality in people who took beta-carotene or vitamin E.

Quality of the evidence
Overall, the certainty of the evidence was considered to be high for any AMD, moderate for late AMD (due to lower number of events), and very low for neovascular AMD or geographic atrophy, which were only reported disaggregated in one study. Although the number of people randomised in these studies was large, there is still a degree of uncertainty in the pooled estimates. In the pooled analyses, the risk ratios were largely around the null value, or just above the null value.

Potential biases in the review process
We did not include the Age-related Eye Disease Study in this review. However, there were 2180 people recruited with no, mild, or borderline AMD (AREDS 2001a). The study reported no benefit of the study treatment for these people, however, the number of events was small.

Agreements and disagreements with other studies or reviews
A review of observational prospective studies in 2007 found little evidence of a protective effect of dietary antioxidants (Chong 2007). The only dietary antioxidant for which a reduction was seen was vitamin E, in contrast to the evidence from the trials included in this review. It is possible that natural vitamin E from dietary sources rather than artificial supplements has different effects, or alternatively, high levels of dietary vitamin E might be a marker for other nutrients. There are many reviews focusing on the role of antioxidant vitamin and mineral supplements in people with AMD, but we have
only identified one that considered specifically their role in healthy people (Zampatti 2014). The conclusions were similar to the current review that there is little evidence for any benefit in healthy people.

AUTHORS’ CONCLUSIONS

Implications for practice

Taking vitamin E or beta-carotene supplements will not prevent or delay the onset of AMD. The same probably applies to vitamin C and the multivitamin (Centrum Silver) investigated in the one trial reported to date. There is no evidence with respect to other antioxidant supplements, such as lutein and zeaxanthin.

Implications for research

There are a number of unanswered questions in the prevention of AMD. The hypothesis that antioxidant micronutrients may protect against the disease is a reasonable one. We do not know at what stage the protective effect may be important, nor the potential interactions with genetic effects and other risk factors for the disease, such as smoking. The research to date suggests that vitamin supplements (at least those studied) do not prevent AMD. They do not provide conclusive evidence on safety. The small number of incident events in healthy people mean that any future trials need to be very large. Four large primary and secondary prevention trials in the field of cancer and cardiovascular disease have added an examination of eye disease. This would seem to be a cost-effective way forward in research in this area.

ACKNOWLEDGEMENTS

This work was undertaken in collaboration with the National Institute for Health and Care Excellence. The views expressed in this publication are those of the authors and not necessarily those of NICE.

We are grateful to:

- the Systematic Review Training Unit at the Institute of Child Health, London for advice on the protocol for this review;
- all the trialists who responded to requests for information;
- peer reviewers Andrew Ness and Usha Chakravarthy for comments on an earlier version of this review.
- Carol Mccletchie OBE who reviewed and commented on the plain language summary from the consumer perspective.

We thank Katherine Henshaw who was an author on the original review. The Cochrane Eyes and Vision editorial team prepared and executed the electronic searches for this review. We are grateful to Anupa Shah and Iris Gordon for their assistance with the review process.

## Characteristics of included studies  [ordered by study ID]

### ATBC 1998

| Methods | Method of allocation: random. Sponsor provided coded capsules  
Masking: participant: yes; provider: yes; outcome: yes  
Exclusions after randomisation: no  
Losses to follow-up: 31%. Random sample for maculopathy study: 9%.  
2 x 2 factorial design. Maculopathy add-on random sample in 2 regions |
|---------|---------------------------------------------------------------------|
| Participants | Country: Finland  
Number of participants randomised: 29,133. Random sample of 1035 selected for maculopathy study  
Age: 50 to 69 years in 1984. Maculopathy study 1992-3 in people aged 65 plus  
Sex: male  
Inclusion criteria: 5 or more cigarettes daily  
Exclusion criteria: history of cancer or serious disease limiting ability to participate; those taking supplements vitamin E, A, or beta-carotene in excess of predefined doses; those treated with anticoagulants |
| Interventions | Intervention:  
• alpha-tocopherol (50 mg/day) N = 237  
• beta-carotene (20 mg/day) N = 234  
• alpha-tocopherol (50 mg/day) and beta-carotene (20 mg/day) N = 257  
Comparator:  
• placebo N = 213  
Duration: 5 to 8 years (median 6.1) |
| Outcomes | AMD: 4 grades:  
Grade I: dry maculopathy with hard drusen, pigmentary changes, or both  
Grade II: soft macular drusen  
Grade III: disciform degeneration  
Grade IV: geographic atrophy  
Quote “A person was considered to have ARM if he had a class I or higher change in either eye, and severity was classified according to the worst eye.” |
| Notes | Compliance with treatment excellent; 4/5 active participants took more than 95% of scheduled capsules. Drop-out rate and compliance similar between all 4 groups  
Funding source: Quote “This study was supported by the Juho Vainio Foundation, Helsinki, Finland. The ATBC study was supported by Public Health Service Contract N01-CN-45165 from the Division of Cancer Prevention and Control, National Cancer Institute of the United States.”  
Declarations of interest: NR  
Date study conducted: Quote “The ophthalmological examination took place during their final follow-up trial visit between December 1992 and March 1993”  
Trial id: NCT00342992 |
### Risk of bias

<table>
<thead>
<tr>
<th>Bias</th>
<th>Authors' judgement</th>
<th>Support for judgement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random sequence generation (selection bias)</td>
<td>Low risk</td>
<td>Quote “The participants were randomly assigned to one of four treatment groups: AT alone, AT and BC, BC alone, or placebo in a complete 2 x 2 factorial design” and “Randomization was performed in blocks of eight within each of the study areas.”</td>
</tr>
<tr>
<td>Allocation concealment (selection bias)</td>
<td>Low risk</td>
<td>Quote “A coded reserve supply of capsule packs...” Not clearly stated that allocation concealed, but the study was described as being “double-blind”</td>
</tr>
<tr>
<td>Blinding of participants and personnel (performance bias)</td>
<td>Low risk</td>
<td>Judgement comment: placebo-controlled study.</td>
</tr>
<tr>
<td>Blinding of outcome assessment (detection bias)</td>
<td>Low risk</td>
<td>Quote “The retinal specialist […] examined six photographs (three per eye) of each participant without knowledge of the subject’s treatment group”</td>
</tr>
<tr>
<td>Incomplete outcome data (attrition bias)</td>
<td>Low risk</td>
<td>Quote “A total of 941 persons participated (91%) and non-participation rates were similar across the intervention groups.”</td>
</tr>
<tr>
<td>Selective reporting (reporting bias)</td>
<td>Unclear risk</td>
<td>Visual acuity measured but not reported, but as the main results for AMD showed no difference between groups, it is not clear whether this was an example of selective reporting or whether, in fact, the investigators considered that visual acuity in this age group might be attributed to a variety of causes, and therefore, was not a relevant outcome</td>

Antioxidant vitamin and mineral supplements for preventing age-related macular degeneration (Review)
**Methods**

Method of allocation: coded tablets  
Masking: participant: yes; provider: yes; outcome: yes  
99% follow-up  
2 x 2 factorial design.

**Participants**

Country: USA  
Number randomised: originally 22,071 men were randomised:  
21,142 participants were followed up for at least 7 years and provided information on diagnoses of AMD made during the first 7 years of the trial  
Age: 40 to 84 years in 1982  
Sex: male  
Inclusion criteria: physician aged 40 to 84 years in 1982 with no history of cancer, myocardial infarction, stroke, or transient cerebral ischaemia  
Exclusion criteria: personal history of cardiovascular disease or cancer; contraindications or current use of study medication;

**Interventions**

Intervention:  
- beta-carotene (50 mg/alternate days) N = 11,036 randomised, 10,585 followed up  
Comparator:  
- beta-carotene placebo N = 11,035 randomised, 10,557 followed up  
There was also an aspirin arm (2 x 2 factorial arm), which was terminated early (January 1988)  
Mean duration 12 years range (range 11.6 to 14.2 years)

**Outcomes**

Self report of AMD followed by medical record review and questionnaire to relevant ophthalmologist  
Primary endpoint: visually significant AMD, defined as a self-report confirmed by medical record evidence of an initial diagnosis after randomisation, but before 31 December 1995, with a reduction in best-corrected visual acuity to 20/30 or worse attributable to AMD  
Secondary endpoints: AMD with or without vision loss, composed of all incident cases; Advanced AMD, encompassed of cases of visually significant AMD with pathological signs of disciform scar, RPE detachment, geographic atrophy, or subretinal neovascular membrane  
Quote "Individuals, rather than eyes, were the unit of analysis because eyes were not examined independently, and participants were classified according to the status of the worse eye as defined by disease severity. When the worse eye was excluded because of visual acuity loss attributed to other ocular abnormalities the fellow eye was considered for classification."

**Notes**

Funding source: Quote “Supported by research grants HL 26490, HL 34595, CA 34944, CA 40360, and EY 06633 from the National Institutes of Health”  
Declarations of interest: NR  
Date study conducted: August 1985 (from clinicaltrials.gov) to December 1995  
Trial id: NCT00000500

### Random sequence generation (selection bias)

**Risk:** Low risk

**Quote:** "The PHS I was a randomised, double-masked, placebo controlled trial..."

"A total of 22,071 physicians were then randomised according to a two-by-two factorial design, with use of a computer-generated list of random numbers...”

### Allocation concealment (selection bias)

**Risk:** Low risk

**Quote:** "The PHS I was a randomised, double-masked, placebo controlled trial...”

**Judgement Comment:** Although this aspect of the trial was not well described, the placebo control was described (placebo and supplement identical appearance and packaging) and the study was described as double-blind.

### Blinding of participants and personnel (performance bias)

**Risk:** Low risk

**Quote:** "The PHS I was a randomised, double-masked, placebo controlled trial...”

**Judgement Comment:** Although this aspect of the trial was not well described, the placebo control was described (placebo and supplement identical appearance and packaging) and the study was described as double-blind.

### Blinding of outcome assessment (detection bias)

**Risk:** Low risk

**Quote:** "The PHS I was a randomised, double-masked, placebo controlled trial...”

**Judgement Comment:** Although this aspect of the trial was not well described, the placebo control was described and the study was described as double-blind. Diagnosis of AMD by self-report based on health questionnaire (confirmed by ophthalmologist or optometrist). Patients and researchers unaware of intervention.

### Incomplete outcome data (attrition bias)

**Risk:** Low risk

**Quote:** "At the end of 11 years of follow-up (the last year completed for all participants), 99.2% were still providing information on morbidity, and the follow-up for mortality was 99.9% complete. Eighty percent of participants in the beta-carotene group and in the placebo group were still taking the study pills, with a mean compliance among pill takers of more than 97%. Therefore, even after 11 years, 78% of the study pills assigned in the beta-carotene group were reported as still being taken. In the placebo group, 6% of participants reported taking..."

### PHS II 2012

#### Methods

- Method of allocation: coded tablets
- Masking: participant: yes; provider: yes; outcome: yes
- 95% follow-up
- 2 x 2 x 2 x 2 factorial design.

#### Participants

- **Country:** USA
- **Number randomised:** 14,236 with no diagnosis of AMD at baseline according to vitamin C/E paper; 14,233 with no diagnosis of AMD at baseline according to multivitamin paper
- **Average age:** 64 years
- **Sex:** male
- **Inclusion criteria:** US male physicians; 50 years and older; participants in PHS I and new physician participants; willing to forego use of supplements for new trial; for new participants, do not report personal history of cancer (except non-melanoma skin cancer). CVD, current liver disease, current renal disease, peptic ulcer or gout. Compliance with pill-taking regimen in run-in period
- **Exclusion criteria:** History of cirrhosis; active liver disease in past six months; participants reporting cataract or AMD at baseline

#### Interventions

- **Intervention:**
  - vitamin E (400 IU/alternate days) N = 7112
  - vitamin C (500 mg/day) N = 7149
  - multivitamin (Centrum silver: zinc 15 mg, vitamin E 45 IU, vitamin C 60 mg, beta-carotene 5000 IU, vitamin A - 20% as beta carotene, folic acid 2.5 mg, vitamin B6 50 mg, vitamin B12 1 mg/ day) N = 7111
- **Comparator:**
  - separate placebos for each type of vitamin: vitamin E placebo N = 7124, vitamin C placebo N = 7087, multivitamin placebo N = 7122
  - Alternate day beta-carotene (50 mg) component terminated in March 2003
  - Lutein (added to Centrum Silver during course of study (250 µg) and doses of other nutrients changed
  - Follow-up: the multivitamin component had a longer duration.
  - “An average of 8 years of treatment and follow-up” for vitamin E and vitamin C
  - Median duration of treatment for multivitamin analyses 11.2 years, IQR 10.7 to 13.3

#### Outcomes

- **Age-related macular degeneration:** reported diagnosis followed up by contact with treating ophthalmologist/optometrist
- **Quote:** “We considered individuals, rather than eyes, as the unit of analysis and we classified individuals according to the status of the worse eye as defined by disease severity. When the worse eye was excluded because of visual acuity loss attributed to other ocular abnormalities, the fellow eye was considered for classification.”
Notes

Funding source: Grants from National Eye Institute, National Institute on Ageing and the National Institutes of Health. BASF and DSM provided study agents and packaging. Declarations of interest: “The authors have no proprietary or commercial interest in any of the materials discussed in this article.”

Date study conducted: July 1997 to June 2011 (from clinicaltrials.gov)

Trial id: NCT00270647

</tbody>
</table>
## Methods

Method of allocation: coded bottles
Masking: participant: yes; provider: yes; outcome: yes
Losses to follow-up: not known

## Participants

Country: Australia
Number of participants randomised: 1204
Eyes: worse eye used as the study eye
Age: 55 to 80 years, mean 66
Sex: 56% female
Inclusion criteria: lens and retina of at least one eye available for documentation
Exclusion criteria: previous cataract surgery or advanced cataract in both eyes; steroid or anticoagulation use; serious disease; regular use or sensitivity to vitamin E

## Interventions

Intervention:
- vitamin E (500 IU/day) natural vitamin E in soybean oil medium N = 595
  randomised, 587 followed up
Comparator:
- placebo identical in sight, taste and smell N = 598 randomised, 592 followed up
Duration: 4 years

## Outcomes

2 m logMAR visual acuity; clinical examination; colour stereoscopic fundus photographs graded using International Grading Scheme
Quote “Participants were categorised by their worse eye.”

## Notes

Funding source: Quote “The VECA T study was funded in part by grants from the National Health and Medical Research Council, the Jack Brockhoff Foundation, the Eirene Lucas Foundation, the Stoicesco Foundation, the Carleton Family Charitable Trust, JeHope Knell Trust Fund, Smith and Nephew, Australia, and Henkel Australia”
Declarations of interest: none declared
Date study conducted: January 1995 to April 1996
Trial id: NR

VECAT 2002

Antioxidant vitamin and mineral supplements for preventing age-related macular degeneration (Review)  
Copyright © 2017 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
tocopherol) in a soybean oil suspension encapsulated in gelatin or a matched placebo capsule containing only the soybean oil.” [...] “Bulk medications were dispensed into labelled jars by a person not involved in the study. Vitamin E and placebo were dispensed on different days to avoid confusion. Identical containers were used. The jars were packed in numerical order and then dispensed by study personnel. Vitamin E and placebo capsules were of identical appearance and taste. Neither study staff nor examiners or participants were aware of the treatment allocation, although all knew that participants would be randomly assigned to receive either vitamin E or placebo.”

**Blinding of outcome assessment (detection bias)**

**AMD**

Low risk

Quote “Neither study staff nor examiners or participants were aware of the treatment allocation, although all knew that participants would be randomly assigned to receive either vitamin E or placebo.” "At the end of the study we reassessed the initial and final photographs for any change with a “side by side” comparison in a masked and randomised fashion”

**Incomplete outcome data (attrition bias)**

**All outcomes**

Low risk

Quote “From the 1906 people who were screened by telephone, 1289 (69%) were examined and 1204 (93%) of these were enrolled and randomised. We excluded 11 participants after randomisation as they were outside the required age range at enrolment.”

“In the vitamin E group, eight people were excluded from final data analysis: six developed diabetic retinopathy, one had myopic degeneration, and one had missing data. Six people were excluded from the placebo group: two developed adult vitelliform macular degeneration and four had missing data.”

Figure 3: 1204 randomised, 11 excluded after randomisation, 14 excluded from analysis: 8/595 vitamin E group and 6/598 placebo group
Selective reporting (reporting bias) | Low risk | Judgement comment: AMD incidence and progression reported but no difference between groups; visual acuity not reported but “Analysis of best corrected visual acuity and visual function data showed no differences between the groups (data not shown) .” Therefore, no evidence that outcomes with “better” results selectively reported

**WHS 2010**

Methods | Method of allocation: random allocation of coded bottles | Masking: participant: yes; provider: yes; outcome: yes | Losses to follow-up: not known

Participants | Country: USA | Number of participants randomised: 39,876 women health professionals | Age: 45+ | Sex: female | Inclusion/exclusion criteria: (a) Female; (b) aged 45 years or older; (c) postmenopausal or with no intention of becoming pregnant; (d) no reported personal history of cardiovascular disease, cancer (other than non-melanoma skin cancer), gout, peptic ulcer, chronic renal or liver disease, or other serious illness precluding participation; (e) no reported history of serious side effects to the study treatments; (f) not currently taking aspirin, aspirin containing medication, or nonsteroidal anti-inflammatory drugs (NSAIDs) more than 1 day per week or, if so doing, willing to forego use of these medications; (g) not currently taking individual supplements of vitamin E or beta-carotene more than 1 day per week; (h) not currently taking anticoagulants or corticosteroids

Interventions | Intervention: | vitamin E (600 IU on alternate days) N = 19,697 | Comparator: | placebo N = 19,724

Outcomes | Self-report and review of medical records | Quote “Individuals, rather than eyes, were the unit of analysis because eyes were not examined independently, and participants were classified according to the status of the worse eye as defined by disease severity. When the worse eye was excluded because of visual acuity loss attributed to other ocular abnormalities, the fellow eye was considered for classification.”

Notes | Funding source: Quote “Supported by research grants CA 47988, HL 43851, and EY 06633 from the National Institutes of Health, Bethesda, Md. Pills and packaging were provided by Bayer Healthcare and the Natural Source Vitamin E Association. Bayer Healthcare and the Natural Source Vitamin E Association had no role in the design and conduct of the study, in the collection, analysis, and interpretation of the data, or in the preparation, review, or approval of the manuscript.” | Declarations of interest: Quote “The authors have no proprietary or commercial interest
in any materials discussed in this article.”
Date study conducted: August 1993 to March 2004
Trial id: NCT00000161

AMD: age-related macular degeneration
### Characteristics of ongoing studies [ordered by study ID]

#### NCT01269697 (LIMPIA)

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>Lutein influence on macula of persons issued from AMD parents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods</td>
<td>Multicentre, double-masked, randomised clinical trial of supplementation with 'Nutrof Total' (lutein and zeaxanthin) versus placebo</td>
</tr>
<tr>
<td>Participants</td>
<td>People at high genetic risk for AMD because their parents had AMD. Age 40 to 70 years</td>
</tr>
<tr>
<td>Interventions</td>
<td>Nutrof Total or placebo</td>
</tr>
</tbody>
</table>
| Outcomes            | Primary outcome measure: Macular pigment density at 6 months after supplementation  
|                     | Secondary outcome measures: 
|                     | Best corrected visual acuity 12 months  
|                     | Cognitive ability 12 months  
|                     | Plasma fatty acids 12 months  
|                     | Macular pigment density during supplementation and after stopping supplementation |
| Starting date       | - |
| Contact information | Jean-Francois Korobelnik  
|                     | jean-francois.korobelnik@chu-bordeaux.fr |
| Notes               | clinicaltrials.gov/show/NCT01269697 |
|                     | The principal Investigator was contacted in March 2016 and confirmed that the study should be published in the next year |

#### SELECT

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>Selenium and Vitamin E Cancer Prevention Trial (SELECT) for prostate cancer</th>
</tr>
</thead>
</table>
| Methods             | This is a randomised, double-masked, multi-centre study. Participants are randomised to one of 4 prevention arms:  
|                     | Arm I: participants receive 2 different oral placebos once daily  
|                     | Arm II: participants receive oral selenium and oral placebo once daily  
|                     | Arm III: participants receive oral vitamin E and oral placebo once daily  
|                     | Arm IV: participants receive oral selenium and oral vitamin E once daily  
|                     | Treatment continues for 7 to 12 years in the absence of unacceptable toxicity or diagnosis of prostate cancer  
|                     | Quality of life is assessed at baseline and then at 1, 3, 5, and 7 years  
|                     | Participants are followed annually |
| Participants        | Healthy male volunteers. A total of 32,400 participants (8100 per prevention arm) will be accrued for this study within 5 years |

Continued

8 November 2007

New citation required and conclusions have changed

Substantive amendment. 2008, Issue 1: The results for PHS I were included. AREDS was previously included in this review but as no numerical data were available from the study on prevention of AMD, it was excluded from the review. The results of AREDS are presented in the review ‘Antioxidants for slowing down the progression of AMD’

CONTRIBUTIONS OF AUTHORS

JE assessed studies for inclusion and exclusion, assessed risk of bias, extracted data, entered data and wrote the text of the review.

JL assessed studies for inclusion and exclusion, assessed risk of bias, extracted data, and reviewed and commented on the text of the review.

DECLARATIONS OF INTEREST

None known.

SOURCES OF SUPPORT

Internal sources

• No sources of support supplied

External sources

• National Institute for Health Research (NIHR), UK.
• Richard Wormald, Co-ordinating Editor for Cochrane Eyes and Vision (CEV) acknowledges financial support for his CEV research sessions from the Department of Health through the award made by the NIHR to Moorfields Eye Hospital NHS Foundation Trust and UCL Institute of Ophthalmology for a Specialist Biomedical Research Centre for Ophthalmology.
• This review was supported by the NIHR, via Cochrane Infrastructure funding to the CEV UK editorial base which funds part of Jennifer Evans’s salary.

The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health.
DIFFERENCES BETWEEN PROTOCOL AND REVIEW

The original protocol was published in 1999 (Evans 1999). Since that time, there have been methodological improvements within Cochrane, and the methods have been updated to include assessment of risk of bias, 'Summary of findings' tables, GRADE assessment, and better consideration of unit of analysis issues.

For the 2017 update, we modified the outcome measures to ensure they were in line with those being used as part of the macular degeneration guidelines being prepared by NICE (NICE 2016). In previous versions of this review the outcomes were:

1. number of participants developing AMD;
2. number of participants with visual loss due to AMD;
3. quality of life measures;
4. any adverse outcomes reported.

In previous versions of this review, we pooled all antioxidants into one analysis. This was not possible in the current version because of overlapping participants in two trials.
