OBJECTIVE — To summarize the efficacy of metformin in reducing BMI and cardiometabolic risk in obese children and adolescents without diabetes.

RESEARCH DESIGN AND METHODS — We performed a systematic review and meta-analysis of randomized controlled trials (RCTs). Double-blind RCTs of ≥6 months duration in obese subjects age ≤19 years without diabetes were included. Our primary outcomes of interest include changes in BMI and measures of insulin sensitivity.

RESULTS — Five trials met inclusion criteria (n = 320 individuals). Compared with placebo, metformin reduced BMI by 1.42 kg/m² (95% CI 0.83–2.02) and homeostasis model assessment insulin resistance (HOMA-IR) score by 2.01 (95% CI 0.75–3.26).

CONCLUSIONS — Metformin appears to be moderately efficacious in reducing BMI and insulin resistance in hyperinsulinemic obese children and adolescents in the short term. Larger, long-term studies in different populations are needed to establish its role in the treatment of overweight children.

Metformin has been shown to reduce weight gain, hyperinsulinemia, and hyperglycemia in adults with type 2 diabetes (1,2) and to reduce progression from impaired glucose tolerance to diabetes in those without diabetes (3). These benefits have led to an increase in the use of metformin in obese children with hyperinsulinemia. However, obesity is not a licensed indication for metformin in the U.K. or the U.S., and its use has proceeded faster than the evidence of its benefits. We undertook a systematic review of randomized controlled trials (RCTs) investigating the efficacy of metformin for reducing BMI and cardiometabolic risk in obese children without diabetes.

RESEARCH DESIGN AND METHODS — We searched Ovid MEDLINE, EMBASE, the Cochrane Register of Controlled Trials, the metaRegister of Controlled Trials, and key journals published before December 2008 (online appendix Tables 1 and 2 available at http://care.diabetesjournals.org/cgi/content/full/dc09-0258/DC1). We included double-blind RCTs of ≥6 months duration with obese subjects age ≤19 years without diabetes and without secondary or syndromic causes of obesity. Primary outcomes of interest were BMI (weight in kilograms divided by the square of height in meters) and measures of insulin sensitivity. Secondary outcomes included fat mass, blood pressure, fasting lipids, and adverse effects.

Where three or more studies reported a common outcome, treatment effect was explored in a meta-analysis (Stata Statistical Software 10.1; StataCorp, College Station, TX), pooling data from the end of the follow-up period for trial completers.

RESULTS — Five studies published between 2001 and 2008 met the inclusion criteria (4–8). Three included one crossover trial (5).

Three studies took place in the U.S. (6–8), and one each in Australia (3) and Turkey (4). All trials lasted 6 months with metformin doses from 1,000–2,000 mg/day. Three studies used lifestyle co-interventions in either trial arms (4,7,8). Two studies included adolescents (ages 12–19 years) (6,7), one looked at younger children (ages 6–12 years) (6), and the others spanned ages 9–18 years. In the U.S. and Australian studies, a large proportion of participants (45–90%) were from ethnic backgrounds with high prevalence of metabolic syndrome (African American, Hispanic, or Asian). All participants were hyperinsulinemic or insulin resistant. Sample size ranged from 28–120 participants at randomization; in total there were 365 participants and 320 trial completers. Mean attrition rates were 11% in metformin groups and 16% in placebo groups.

In the pooled analysis, metformin reduced BMI by a mean of 1.42 kg/m² (95% CI 0.83–2.02) compared with placebo (I² = 56.2%; n = 342) (Fig. 1). Sensitivity analyses did not reveal notable differences by age, dose, or baseline BMI. When the outlier result was excluded, metformin reduced BMI by 1.15 kg/m² (0.73–1.57, I² = 0%). Reduction in fasting insulin was greater in metformin than placebo groups in three studies, but evidence for a treatment effect was weak (~5.30 µU/ml [95% CI −11.96 to 1.36], I² = 78.7%; n = 257) (4–7). Pooled metformin effect on the homeostasis model assessment of insulin resistance (HOMA-IR) score was −2.01 (95% CI −3.26 to −0.75, I² = 49.5%; n = 234) (4,6,8) and −1.28

Metformin for obesity in children and adolescents

Pooled mean metformin effect on total cholesterol was $-0.19$ mmol/l (95% CI $-0.38$ to $-0.01$, $I^2 = 0$%; $n = 234$) (4,6,7). Analyses did not provide strong evidence for a treatment effect on fasting glucose, HDL cholesterol, triglyceride levels, or blood pressure. There was insufficient data to comment on body fat outcomes. Gastrointestinal problems were the most common reported side effect (in 20–30%) and were more frequently reported in metformin than in placebo groups (risk difference 10–14%) (6,7). Only one participant reported gastrointestinal problems as the reason for leaving a study (7).

CONCLUSIONS — Our meta-analysis provides some support for a beneficial metformin effect on obesity outcomes among hyperinsulinemic children and adolescents. Treatment over 6 months may be efficacious in reducing BMI by $1.42$ kg/m$^2$ (equivalent to 0.6 SD, based on SD for BMI in U.K. and U.S. adolescents) and HOMA-IR score by $2.01$ ($-0.67$ to $-1.34$) at 6 months (95% CI $-0.62$ to $-0.28$).

To our knowledge, the effects of metformin on BMI in obese children without diabetes have been synthesized in only one published review based on three studies (11), which identified no treatment effect at 6 months ($-0.17$ kg/m$^2$ [95% CI $-0.62$ to $-0.28$]). Metformin may not be as effective as behavioral interventions in reducing BMI: a meta-analysis of behavioral interventions in obese adolescents reported an effect of $3.04$ kg/m$^2$ (95% CI $3.14$ to $2.94$) at 6 months, which was maintained at 12 months follow-up (12). When compared with drugs that are licensed for obesity, metformin has moderate effect: meta-analyses of RCTs reported an orlistat effect of $0.76$ kg/m$^2$ ($1.07$ to $0.44$) and a sibutramine effect of $1.66$ kg/m$^2$ ($1.89$ to $1.43$) at 6 months (12).

The results of this review must be interpreted with caution: the studies were short-term and based on small samples; participants were mainly from the U.S., and large portions were from ethnic backgrounds known to be at increased risk of metabolic disorders, limiting the generalizability of findings; and the studies presented unadjusted measures without intention-to-treat analyses, which may have overestimated treatment effects.

Metformin may be efficacious in reducing BMI and insulin resistance among obese hyperinsulinemic children and adolescents in the short term. Larger, long-term studies across different populations are needed to establish the role of metformin as therapy for obesity and cardiometabolic risk in young people.
