What is already known on this topic

Little is known about the prevalence of sexual dysfunction in people attending their general practice and whether such problems are recognised by doctors.

Controversy exists about defining sexual dysfunction in terms of health and disease.

What this study adds

22% of men and 40% of women received at least one ICD-10 diagnosis of sexual dysfunction according to stringent clinical criteria.

Older women with poorer physical and psychological function and who were dissatisfied with their sex life were more likely to have a ICD-10 diagnosis of sexual dysfunction, as were bisexual men.

Although similar findings have been reported in men who report same sex behaviour,1 to our knowledge no other population study has focused specifically on sexual problems in bisexual as distinct from homose- 

sexual men.

Sexual function problems and help seeking behaviour in Britain: national probability sample survey

Catherine H Mercer, Kevin A Fenton, Anne M Johnson, Kaye Wellings, Wendy Macdowall, Sally McManus, Kiran Nanchahal, Bob Erens

The need for estimates of the extent of sexual function problems in the general population has become more urgent given recent debates surrounding the identification and definition of “sexual dysfunction,” the increased availability of pharmacological interventions, and possible changes in our expectations of what constitutes sexual function and fulfilment.1 We report results from the national survey of sexual attitudes and lifestyles (Natsal 2000).

Participants, methods, and results

Natsal 2000 was a stratified probability sample survey done between May 1999 and February 2001 of 11 161 men and women aged 16-44 years resident in Britain.2,3 The response rate was 65.4%. A computer assisted self interview asked participants about their sexual lifestyles and attitudes. We asked questions about their experience of sexual problems based on those used in the US national health and social life survey,4 which measured the main dimensions of sexual dysfunction, as defined in ICD-10 (international classification of diseases, 10th revision). We analysed data in STATA accounting for the sample’s stratification, clustering, and weighting.1,5

A total of 34.8% of men and 53.8% of women who had at least one heterosexual partner in the previous year reported at least one sexual problem lasting at least one month during this period (table). The most common problems among men were lacking interest in

*The base for sexual problems lasting longer than six months is slightly smaller than the base for any sexual problems reflecting non-response to the question which asked how long problems had lasted.

in sex, premature orgasm, and anxiety about performance; and among women, inability to experience orgasm and painful intercourse.

Persistent sexual problems—lasting at least six months in the previous year—were less prevalent among men (6.2%) than among women (15.0%). The most common persistent problem among men was premature orgasm and among women, lack of interest in sex.

Among people who had sexual problems, 32.5% (95% confidence interval 29.7% to 35.3%) of men and 62.4% (60.4% to 64.3%) of women avoided sex because of their problems. Only 10.5% (8.8% to 12.4%) of men and 21.0% of women (19.3% to 22.7%) with problems in the previous year sought help. People with persistent problems were more likely to have sought help (29.3% (15.8% to 26.3%) of men and 31.9% (28.4% to 35.5%) of women). Among people seeking help, 63.8% (54.6% to 72.1%) of men and 74.3% (70.1% to 78.1%) of women consulted their general practitioner, and 9.2% (5.3% to 15.4%) of men and 4.8% (3.2% to 7.2%) of women sought help at a genitourinary clinic.

**Comment**

Problems of sexual function are relatively common, but persistent problems are much less so. Inconsistent definitions make comparing prevalences with other studies difficult. Given the broad spectrum of problems, we have not sought to define clinical ‘dysfunction’ but rather to describe the range of problems of sexual function in the population and to use duration of problems and avoidance of sex as indicators of severity. We asked specifically about problems that lasted more than one month in the previous year; but whether, for example, lacking interest in sex can be considered as “dysfunction” is questionable since it was reported by two fifths of women and one fifth of men.

Few people sought help with their problems reflecting how severity varies, and how the need for professional intervention depends on the perceived importance to the patient and the underlying causes. Seeking help also reflects awareness of the availability of advice and treatment; more men present with sexual problems at genitourinary clinics since the licensing of sildenafil. People who often seek help consult their general practitioner but given the limited time and resources in this setting, such problems may be accorded low priority.

Our data have implications for improving relationship education, counselling, medical education, and ‘doctors’ professional development; raising public awareness of the range and location of services available for managing sexual problems; and re-examining the nature of "sexual dysfunction" and how best to tackle it.

**Endpiece**

**Angry**

Anyone can be angry—that is easy. But to be angry with the right person, to the right degree, at the right time, for the right purpose, and in the right way—this is not easy.
