Chapter 2

Health systems and institutions

Lucy Gilson

2.1 Introduction

As outlined in Chapter 1, richer understanding of the dynamics of health sectors is necessary in thinking through how to strengthen the health system and enable performance improvements in health sectors [1,2]. To support such understanding, this chapter adopts an institutional lens in considering both the nature of health systems and ways of strengthening them.

Building on Chapter 1, five widely known health system conceptual frameworks are reviewed first. The review highlights the different types of agents, organizations, and organizational arrangements that are embedded within each framework, and seeks to identify the nature of relationships among actors, and the institutions each identifies or implies as underpinning these relationships. Second, recent thinking on health system governance—a central, but less considered, function of every health system that is particularly relevant to health system strengthening—is presented. Third, three complementary bodies of theory (organizational and policy implementation theory, and systems thinking) that draw on institutional perspectives in considering organizational functioning and change, are briefly presented and applied in critique of the health system frameworks. The critique highlights the dominance of a mechanical perspective of organizational functioning within existing frameworks, and a primarily command and control approach to health system strengthening.

Finally, two alternative approaches to supporting change within health systems, both of which acknowledge complexity and seek institutional change, are introduced: soft systems methodology and strengthening trust-based relationships.

The concept of an institution is central to this discussion. Where organizations are the social settings within which activities take place, institutions are the rules, laws, norms, and customs that shape behaviour in those settings, generating patterned or shared behaviour over time among groups of actors involved in specified relationships with each other [3]. It has been argued that such institutions have three main components: the regulative pillar of rules that constrain and regulate behaviour (commonly understood to include
economic incentives); the normative pillar of norms and values that confer both responsibilities that constrain social behaviour, and rights that enable social action; and the cultural-cognitive pillar of shared routines, conceptions, and frames through which meaning is made [4]. Although institutions are fairly stable social structures they can and do change over time because there is a two-way process of influence: individual preferences and values are both shaped by, and shape, institutions [3].

2.2 Conceptualizing health ‘systems’

Five conceptual frameworks are discussed here, allowing examination of different and changing understandings of the nature of a health system, thus complementing Chapter 1. In order of chronological development, these are: Roemer’s 1991 outline framework [5]; the World Health Organization’s (WHO’s) 1993 health care financing framework [6]; Frenk’s 1995 relational framework [7]; WHO’s 2007 version of the building block framework [1]; and Roberts et al.’s 2008 ‘control knobs’ framework [8].

2.2.1 A focus on health care or on health?

Of these five frameworks, three focus squarely on health care and health services [5–6,8]. Only two encompass activities relevant to promoting, restoring, or maintaining health (but see also [9], discussed in Chapter 10). The Frenk framework [7], for example, includes other sectors and their production of services with health effects. It also gives the population, through community participation, a role in and influence over health care organizations, as well as recognizing its role in providing people, money, and data for the overall system. The broader focus of the WHO building block (WHO BB) framework [1] is more hidden. However, it describes the health information system as encompassing the collection and use of information on ‘health determinants, health systems performance and health status’, and notes that leadership/governance includes concern for the health-promoting actions of other government sectors.

2.2.2 An inventory or relational approach?

Both the WHO BB framework [1] and Roemer [5] appear to adopt an inventory approach [7] to understanding a health system: that is, they identify a set of core functions but do not specify the health system actors engaged in these functions nor the relationships among them. Figure 2.1, thus, gives no sense of the interactions among health system building blocks, nor how they impact on performance outcomes. Similarly, although Figure 2.2 signals interactions
among a set of five health system functions that result in service delivery, it
does not clarify their basis or nature: ‘These types of approaches are helpful for
describing health systems… However, the categorizations are less helpful for
understanding how well health systems perform. This would require more
detailed subcategories and greater elaboration of the relationships within each
category but particularly between categories’ [10, pp.514–15].
Nonetheless, the report presenting the WHO BB framework notes that
‘A health system, like any other system, is a set of inter-connected parts that
must function together to be effective. Changes in one area have repercussions

![Fig. 2.1 WHO BB [1] framework.](image)

![Fig. 2.2 Roemer [5] framework.](image)
elsewhere. Improvements in one area cannot be achieved without contributions from the others. Interaction between building blocks is essential for achieving better health outcomes [1, p.4]. This relational nature of health systems is more clearly represented in the next two frameworks discussed.

Four functions required in any health system (regulation, financing, resource allocation and service provision) are identified in the WHO health care financing (HCF) framework [6] (Figure 2.3), as well as four agents and the relationships among them that underpin the functions. Although not discussed in any detail, the figure also highlights the key institutions that shape these relationships: regulatory authority (based on rules and involving sanctions or economic incentives); payments by patients/population (economic incentives); and provider claims on financing agents (underpinned by rules) (Box 2.1). In a further specification of the framework, government’s regulatory role is noted to include structuring the system in line with social consensus on the ethical principles (e.g. ability to pay or social rights) on which it is founded [10].

A more complex set of dynamics among elements of the health system, and between them and the external environment, are represented in Frenk’s framework [7] (Figure 2.4).

In illuminating this complexity, the framework highlights, first, the various roles played by the state (the collective mediator), noting that ‘there are many public agencies that are not part of the health system per se, but that constitute a key element of its organizational environment. This is the case of the legislative and judicial branches of government, as well as the executive officers dealing with public budgets, taxation and law enforcement. We may conclude, therefore, that the state occupies multiple positions in the health system and its environment’ [7, p.27]. Figure 2.4 shows that the state exercises control over health sector agents (here, health care providers and resource generators),
Box 2.1 Health system relationships and their institutional bases [6]

- **Government/professional body and providers**: regulatory authority used to secure, e.g. available and good quality service provision to patients.
- **Government/professional body and financing agents**: regulatory authority used to, e.g. contain costs for patients (controlling pricing and reimbursement levels).
- **Patients and providers**: financial payments exchanged for service provision.
- **Population and financing agents**: financial payments exchanged for insurance coverage.
- **Providers and financing agents**: claims (based on service provision to clients) exchanged for resource allocation (using funds raised from the population).

Fig. 2.4 Frenk [9] framework.
through some combination of financing, regulation and direct delivery of
services (in effect, ownership). However, it also exercises control over other
sectors (recognizing variations among systems in the degree to which broader
health promoting functions rest in other sectors) and explicitly acts as the
mediator between patients and providers. Finally, the state’s relationship to
the population involves, on the one hand, offering the subsidies, information,
and ideologies that shape population interactions with the health sector and,
on the other hand, is based on the basic eligibility principles on which the
health sector is founded (which vary between countries from purchasing
power, to poverty, to the socially perceived priorities accorded particular pop-
ulation groups, to citizenship). The relationship between the state and the
population is thus itself influenced by the prevailing sociocultural norms or
consensus that is embedded in these principles.

Indeed, the second layer of complexity embedded in Figure 2.4 is its recogni-
tion of both the layers of exchange embedded within health system relation-
ships and the range of institutions underpinning them. Considering the
relationship between the population and health care providers, Figure 2.4
indicates that the provision of taxes and demand for services is exchanged for
service delivery. However, the figure also shows that the population not only
receives services from providers, but also participates in decision-making with
health care providers, or about them. The nature of these exchanges suggest
that the underpinning institutions are likely to comprise economic incentives,
the rules of decision-making and the norms and values demonstrated by each
actor through the experience of decision-making. Health care providers, for
example, not only deliver care to the population, but also offer frameworks for
interpreting human experience to patients. Frenk [9, p.27] explains these as
‘alternatives to magical and religious explanations [presumably of health and
illness] that can be used to legitimize modernizing ideologies and to exercise
control over the population (for example, in such cases as infectious diseases
and mental disorders)’. Providers, thus, offer new frames of understanding,
new norms, to shape health seeking behaviour and legitimize health care inter-
ventions. Finally, as members of the population and individual providers
belong to various organizations at the same time, these organizations (the
interests of which may themselves conflict) also influence their members’
interactions with other actors.

2.2.3 Descriptive, analytical, or predictive?
The four frameworks so far presented either describe health system compo-
nents [1,5], or support analysis of their functions and operations [6,7]. The
framework of Roberts et al. [8], illustrated in Figure 2.5, goes further, seeking
to answer the question, ‘what factors influence how well the functions perform in a system?’ [2, p.9].

Focused only on health care, this framework identifies five ‘control knobs’ that can be adjusted by government action to influence the relationships among health system elements. Although several of these knobs resemble the functions of other frameworks, they are seen here as ‘power mechanisms’ through which actors adjust the health system and generate measurable changes in system outcomes [2]. As Table 2.1 illustrates, they do this by adjusting the institutional drivers of the behaviour of health system agents.

</tr>
</tbody>
</table>
The health system strengthening interventions highlighted by this framework include those discussed in the health reform debates of the 1990s [10,11], such as financing, resource allocation, regulatory and service delivery reforms. Possible organizational reforms include changing: the mix of organizations or division of tasks among them, through, for example, privatization; the interactions among health sector agents and their relationship with the rest of the system, through strategies that change incentives such as competition or contracting out; or what happens inside health care organizations through decentralization, total quality management, and other types of management strengthening or corporatization. Reforms focused on the behaviour knob, meanwhile, include quality improvement programmes targeting provider behaviour and social marketing programmes targeting patient behaviour. In broad terms, this knob acknowledges the importance of provider–patient and state–patient relationships in overall health sector and system performance.

However, Roberts et al. [8] emphasize that achieving performance and equity improvements also demands paying careful attention to six steps in the reform process:

1. Clarifying goals and related policies, prioritizing among the range of performance outcomes through ethical reflection, as well as political and technical analysis of feasibility.
2. Carrying out an honest diagnosis of current problems, to identify where action is required.
3. Developing a plan that can be realistically expected to work in a specific national context; recognizing also that the process of plan development will itself influence its acceptability to key actors and interest groups.
4. Embracing politics: health sector change affects interest groups differently and is subject to broader contextual changes, so all reform processes require active political management.
5. Focusing on implementation, as health sector actors often resist change, either from self-interest or anxiety, and it is always necessary to keep an eye on results and outcomes.
6. Learning from mistakes—even successful reform generates new problems.

2.2.4 Recognizing international influences?
None of these five frameworks consider international influences. Yet, as discussed in more detail in other chapters (especially Chapters 8–11), international factors directly impact on national health systems, through trade in goods, services, and people, and related international agreements, bio-technological
advances, and through levels of, and approaches to, channelling, financial and
technical support. They also indirectly impact on the causes of disease, to which
health systems must respond, and, by influencing the wider economic situation,
on national health funding levels. Finally, international factors have influenced
the institutional underpinnings of health sectors: for example, the market-
oriented health sector reforms promoted by international agencies have impli-
cations for the eligibility principles (or social contract) of some national health
sectors [12]. Future conceptualization of health systems must, therefore, recog-
nize that national health systems are open systems that interact with their exter-
nal environment, including international factors (for example, by adopting the
systems thinking approaches discussed later).

2.3 Governance and governance reforms

Although not well reflected in Figure 2.1, the function of governance is some-
times portrayed in the WHO BB framework as the central point around which
the other building blocks turn (reflecting the collective mediator of Frenk [7],
Figure 2.4). Synonymous with the notion of stewardship, it involves the pro-
tection of the public interest or ‘the careful and responsible management of the
well-being of the population’ [13, p.2]. More specifically, governance involves
guiding the whole health sector through six subfunctions that emphasize both
some areas of health sector reform and the need to pay attention to the reform
process (Table 2.2).

However, an explicit focus on governance also offers new insights about
health system relationships and the actions required to strengthen them. The
dominant institutions underpinning these relationships are not economic
incentives and regulatory rules. Instead they are the rules, norms and values
that confer responsibilities and rights. These ‘can be both formal, embodied in
institutions (e.g. democratic elections, parliaments, courts, sectoral minis-
tries), and informal, reflected in behavioural patterns (e.g. trust, reciprocity,
civic-mindedness)’ [14, p.3]. Power is also recognized as a dimension of rela-
tionships, with the state and providers seen to be generally more powerful than
citizens. The focus on governance, thus, clearly highlights the normative insti-
tutional pillar of any health system.

From this perspective, health governance is about putting in place effective
rules that ‘condition the extent to which the various actors involved fulfil their
roles and responsibilities, and interact with each other, to achieve public pur-
poses’ [14, p.3]. When these interactions operate well they ensure:

1 Some level of accountability of key actors to the beneficiaries and broader
   public;
1 A policy process that engages key and competing interest groups on equal
terms (given fair rules of competition), and allows negotiation and compro-
mise among them;

2 Sufficient state capacity, power and legitimacy to manage policy making
and implementation processes effectively; and

3 Engagement by non-state actors in policy processes, service delivery part-
nerships and in oversight and accountability.

4 Health system governance must, thus, seek to strengthen the critical proc-
esses through which norms and values are demonstrated, and rules established. 

Reflecting Table 2.2, such action might include: more effective engagement 
with policy actors and better use of information in the policy process (influ-
encing interactions between citizen and state, and state and providers);
enhanced community participation (influencing interactions between citizen
and state, and citizens and providers); and increased accountability and trans-
parency, reducing corruption (influencing interactions among all three sets of
actors).

2.4 Insights from wider theory relevant to health

systems debates

The insights of three different and overlapping bodies of conceptual thinking
are briefly presented in this section, and used both to examine the health sys-
tem frameworks and think further about health system strengthening.

2.4.1 Understanding organizations

Although not a comprehensive theoretical overview (for that see, e.g. [15]),
Table 2.3 summarizes three perspectives which illuminate different facets of
organizational realities [16]. The machine perspective sees organizations as
hierarchical arrangements of defined components that work together effi-
ciently and reliably, as in an idealized bureaucracy. The variability of human
behaviour is more or less written out of organizational life in this perspective.
Instead, as Table 2.3 suggests, people working within an organization are
assumed simply to comply with changes, responding to the exercise of organi-
zational authority and related rules and procedures. The economic perspec-
tive, meanwhile, suggests that rather than controlling people through rules,
‘the self-interested behaviour of people needs to be taken into account in the
structuring of institutional arrangements… [and also]… provides a means of
control and motivation’ [16, p.15]. This perspective suggests that economic
incentives rather than rules represent the institutional basis of organizations.

The WHO BB [1] and Roberts et al. [7] frameworks (Figures 2.1 and 2.5)
seem to reflect the institutional understandings of some combination of these
two perspectives; and the WHO HCF framework [6] (Figure 2.3) clearly
reflects the economic perspective. Not surprisingly, therefore, the health sector
reforms they emphasize (see Table 2.3) include standardized packages (such as
decentralization, packages of care), those intended to encourage market-type
relationships or strengthen financial incentives and the use of scientific
evidence to identify the best technical solutions.

The sociocultural perspective, in contrast, sees organizations as networks or
clans. It emphasizes that the behaviour of those working in organizations is
fundamentally influenced by social relationships, and by both the norms and
values and shared social meanings embedded in them. A growing body of
empirical evidence also confirms this unpredictable human element within

</table>
health systems. In Nepal, for example, the contradiction between the values-in-use of district health staff and the values expected to support bureaucratic functioning resulted in training interventions rarely improving performance [17]. Similarly, there is Indian evidence that the disjunctions between the ideals and practice of health system supervision and disciplinary action reflect local level norms and power relations [18]; and evidence from Pakistan shows how societal gender norms infuse health system management, making working life difficult for female health workers [19].

This sociocultural organizational perspective is most clear in Brinkerhoff and Bossert’s governance framework [14], although that tends to emphasize rights and responsibilities over shared social meanings as the institutional basis of health systems. The Frenk framework (Figure 2.4) also acknowledges social relationships, values and a range of institutional influences over behaviour, but the Roberts et al. framework (Figure 2.5) only hints at this perspective (in highlighting the importance of managerial changes in promoting better performance, in combination with economic incentives).

2.4.2 Understanding policy implementation

Policy analysis theory broadly considers how ideas, interests, and institutions play out in policy-making and includes theoretical perspectives on the processes of policy implementation. Understanding implementation as the interaction between policy and action, this body of theory is clearly relevant to thinking about how to strengthen health systems and has overlaps with organizational theory (see Table 2.4).

The mechanical model of implementation, for example, reflects the organizational machine perspective and both are rooted in reductionist thinking that simplifies complexity by dividing a problem into subproblems. In implementation this process is translated into a rational planning and management approach involving a linear sequence of activities controlled by policy actors at the centre or top of the organization [20]. Working through economic incentives rather than rules, the economic perspective on organizations also commonly assumes such a top-down approach to reform implementation [21].

In contrast, the cultural model of the policy-action relationship reflects the sociocultural perspective on organizations, illustrating the ways in which the human dimension of organizations plays out in policy implementation. This model and related work showing the influence of organizational culture on organizational performance [22,23], emphasize the influence of shared social meanings over policy implementation. The political model (Table 2.4), meanwhile, reflects a more political view of organizational life than so far discussed. It emphasizes the power relationships among actors between and within organiza-
tions, including the discretionary power of implementing actors who work at the local level, such as front-line providers [24], and of beneficiaries [25]. Environmental health officers in Ghana [26], for example, and community health workers in Brazil [27], exercised their power to support policy implementation; whereas in South Africa [28] and Tanzania [29] resistance from local level health workers and managers undermined the achievement of policy objectives.

These two implementation models suggest, therefore, that policy implementation is a much more negotiated and contested process than that envisaged in the mechanical model. Indeed, where this latter model suggests that implementation can essentially be commanded by those at the top, the bottom up perspectives of the other models indicate that implementation should be regarded as ‘...a policy-action dialectic involving negotiation and bargaining between those seeking to put policy into effect and those upon whom action depends... Policy may thus be regarded as a statement of intent by those seeking to change or control behaviour, and a negotiated output emerging from the implementation process’ [21, p.253].

Given their largely mechanical and economic bases, health system frameworks are, however, often linked to a rational and top down perspective on

</tbody>
</table>

how to implement change [30]—even when recognizing the importance of managing the politics of change. The institutional bases of resistance to, and so contested processes of, implementing change within health systems are essentially ignored.

2.4.3 Understanding systems

The ways in which ‘systems thinking’ see any system, including a health system, was highlighted in Chapter 1. Although more widely recognized in high-income countries, such thinking is only just beginning to influence work of relevance to health systems in other settings. The approach offers new insights into the complex and relational nature of health systems and their sociocultural bases, going well beyond the complexity presented in the Frenk [7] framework.

Of particular relevance to this discussion, and reflecting the sociocultural organizational perspective and the cultural model of policy implementation, is the insight that agents in a system respond to their environments using internalized rules, ‘instincts constructs, and mental models’ [31, p.626]. In the form of institutional memory, some rules are shared across a system, but others may not be shared and may change over time. Emerging from the interactions among its agents, the behaviour of the system is, therefore, often unpredictable, generating unexpected (and sometimes creative) outputs [32].

Further comparison of a systems thinking perspective on organizations with that of the machine and economic/market perspectives, shows different understandings of relationships and diversity (Table 2.5). It also makes clear the systems thinking contributions on learning, power and the importance of the local, rather than central, level. Reflecting bottom-up implementation theory, a systems thinking perspective suggests that efforts to implement policy through a top-down approach are ‘doomed to failure because policy makers neither command nor control the whole of the system. Worse still attempts to impose command and control can end up destroying the system’s ability to adapt—or, in other words, restrict its ability to learn and adapt in the face of a changing environment’ [33, p.203].

Atun and Menabde [34] argue that the characteristics of health systems, such as the many interacting feedback loops and the unpredictability of intervention outcomes, clearly show the relevance of systems thinking to health systems. The health system barriers to TB DOTS implementation in the Russian Federation, for example, included the inherent disincentives created by existing financing and provider payment systems and organizational structures, as well as the political difficulties of required reductions or re-allocations of staff posts and the sociocultural norms which underpinned staff resistance
to an externally developed programme. Thus, ‘the context, the interaction between health system elements and context-health system interactions affect the way rules norms and enforcement mechanisms are interpreted to generate response that may not be easy to predict and may indeed be counter-intuitive’ [34, pp.133–4]. Importantly, context is understood here as encompassing the values, norms, and understandings shaping the behaviours and relationships of health system actors, rather than only referring to more material and structural factors [36].

2.4.4 Summary

All three bodies of theory presented here affirm the relational nature of health systems and the wide range of institutional influences embedded within them. The drivers of actor behaviour go beyond rules and financial incentives to include their relationships with others, the wider set of norms, values, and, importantly, shared meanings that underpin those relationships, and conflicting interests and relative power. Policy implementation theory and systems
thinking also emphasize the importance of the local, rather than central, level in strengthening systems. Local level forces are the vital influences over system performance, and local actors, the ultimate implementers of any policy change.

In contrast, as Table 2.6 shows, current health system frameworks are imbued with a mechanical perspective on health systems, and a command and control approach to health system strengthening. The relational nature of the health system, its dynamic complexity, is perhaps most fully reflected in Frenk [7] and Brinkerhoff and Bossert [14] frameworks. However, neither offers much guidance on how to work with that complexity in seeking to strengthen health systems.

2.5 Enabling system governance

The bodies of theory examined in Section 4 suggest that health system strengthening will be better supported by participatory implementation approaches that seek to manage meaning and strengthen the norms and values shaping actor behaviour, rather than working primarily through rules, authority and economic incentives. But how can local level actors be engaged? Two complementary insights are drawn from the theoretical perspectives considered here.

First, a systems thinking perspective suggests that problem-solving must be based on testing and learning from action, rather than predominantly applying reductionist and rational approaches. The complexity of systems makes anticipating problems almost impossible. Instead systems must support local-level learning over time by encouraging open relationships and free exchange among system actors [32]. Such learning is ‘more about problem coping than problem solving’ [33, p.21].

Systems thinkers argue that whilst central planners ought to establish the general direction of the change they seek and the limits of the change they would find acceptable, they should allow local flexibility in achieving those goals and in resource use. Learning is fostered by encouraging experimentation, diversity, and reflection—and embracing both success and failure [37, 38].

Soft systems methodology (SSM) is an approach to such learning. It is particularly relevant where operational staff are seen to be influential and their ownership of improvements is essential for bringing about change [37], or where managers within organizations are willing to learn from the new ideas and perspectives of actors outside the system [33]. Undertaken by those directly involved in the area of concern, it involves groups of people working together to: explore the problem situation; develop an idealized model of how to transform it; identify the feasible and desirable changes required to bring about such transformation; taking any of those actions that they can; and, finally, reflecting and repeating the cycle of action and learning.

There are three key aspects of SSM analytical approaches and tools. They require iterative processes of action and learning. They allow multiple perspectives to be gathered about current challenges and ways of working differently. They seek to understand the complex chains of interactions underlying current problems as a basis for identifying the key points through which managerial action can leverage cycles of improvement. Some tools also allow consideration of who has to act differently in bringing about improvement. Hard analytical methods, such as cost-effectiveness analysis, may be used
depending on the nature of the problem [39]. Nonetheless, the main strength of SSM ‘is its ability to bring to the surface different perceptions of the problem and structure these in a way that all involved find fruitful. Because the process is strange to most participants, it also fosters greater openness and self-awareness. The process is very effective at team-building and joint problem-solving’ [37, p.76]. On this basis, a ten-step approach to designing and evaluating health system strengthening interventions that is rooted in wide stakeholder involvement, including front-line providers, and knowledge sharing has been proposed [38].

Second, trusting relationships are commonly acknowledged as a critical basis for encouraging learning. ‘For individuals to give of their best, take risks and develop their competencies, they must trust that such activities will be appreciated and valued by their colleagues and managers. In particular, they must be confident that should they err they will be supported, not castigated. In turn managers must be able to trust that subordinates will use wisely the time, space and resources given to them through empowerment programmes and not indulge in opportunistic behaviour. Without trust, learning is a faltering process’ [40, p.65]. Trust is also identified, along with rules and contracts, as one of three possible bases for policy implementation and local management [41]. Indeed, given the distribution of power within them, implementation (or co-production) through local actor networks within and across organizations requires a more persuasive approach to management than that associated with rules or contracts.

Trust is often seen to be of particular importance to health due to the uncertainty and unpredictability of ill-health, and the influence of trusting relationships over caring behaviour [42, 43]. For instance, four detailed South African case studies of primary care facilities showed widespread distrust in the employer. Yet in the two better performing facilities (as assessed by health care managers, health facility users, and researcher observation), there was also higher staff motivation levels (assessed qualitatively), some degree of trust in colleagues and the manager was widely trusted. In contrast, in the worse performing facilities, there were lower staff motivation levels and little trust in colleagues or the managers [44].

Although not yet well developed, ideas about how to develop trust within health sector relationships highlight the importance of strengthening both inter-personal behaviours and the institutions shaping them. Relevant inter-personal behaviours include competence, sincerity, empathy, altruism, fairness and reliability; and these are enabled by institutions that allow the trustor to judge whether the trustee will act in her best interests or, at least, without malice. Such institutions encompass all three institutional pillars: organizational
roles and procedures, rules and legal frameworks, and the communication and
decision-making practices that generate shared meanings. They generate, in
particular, information about how people are treated by others and the values
driving their behaviour, and support the development of mutual understand-
ing and shared interests. Indeed, it is often said that trust is constructed through
use and worn out by dis-use [45].

In thinking about how to develop trust it is also necessary to acknowledge
power: whilst trust may provide the basis for the exercise of legitimate power,
trusting too much, without caution, may lead to the abuse of power [45].
Thus, where communication practices are strongly influenced by the underly-
ing power relationships between actors, trust may be coerced and so illegiti-
mate. Voluntary trust can only be generated when communication is ‘sincere,
open and directed towards achieving understanding and consensus’ [46,
p.437]. This represents a particular challenge for health systems given that the
taken-for-granted power of the doctor or the system commonly results in
‘instrumental and non-participatory communication based on the belief that
the bio-medical approach is “right”’ [47, p.1458].

Nonetheless, if managed carefully, participatory management approaches
can provide opportunities to build trust. The application of soft system
methodology, for example, may generate trust when based on open communi-
cation and dialogue among those involved, and the development of shared
interests. Their use may, then, also, provide the basis for the co-production
necessary to implement agreed actions. However, some initial trust will be
needed to encourage open communication and draw in multiple perspectives.
So in using these, or other participatory management, approaches it is impor-
tant to pay particular attention to the procedures of dialogue, the provision
of institutional guarantees of trust and to limiting the exercise of power
during discussions [14, 47]. Other possible arenas and approaches for the
trust-generation that can strengthen health system performance are summa-
ized in Table 2.7.

2.6 Implications for health system strengthening
Health systems and health sectors within those systems comprise sets of rela-
tionships. However, the institutional foundations of these relationships are
commonly seen through lenses that emphasize rules and economic incentives.
Only the more recent governance frameworks give clearer attention to the
norms and values that underpin systems, and there remains little considera-
tion of the shared social meanings that shape individual and organizational
performance.
In low- and middle-income countries, health reform debates, action to strengthen health sectors has, meanwhile, often been portrayed as a centrally controlled intervention involving particular sets of structural or incentive reforms. In essence, the reformer is seen as an actor intervening from above and outside who adjusts the rules of the game (e.g. through control knobs) that other health actors play. Although there is growing recognition of the importance of adapting reforms to particular contexts on the basis of both careful diagnosis of the problems facing any health system and a deliberate process of managing change, the reformer is still commonly seen as a rational deus ex machina [8].

In contrast, this analysis argues that the complexity of health systems and sectors means that it is difficult to strengthen them through central action. Effectively implementing any change requires understanding implementation as the ‘enculturation of change’ [21, p.260]. It requires re-wiring the institutional drivers of

local level behaviour and relationships to sustain new practices or activities. That
means paying more attention to the inner workings of the system, and parti-
cularly to the overlooked institutions of norms and values, including trust, and
shared social meanings, rather than to its outer structure of rules and incentives.
Central level guidance for action must, therefore, be combined both with the
local level learning that allows new ideas and interventions to be adapted effec-
tively to local circumstances, and with deliberate action to build trusting rela-
tionships. This is the crux of health system governance, a critical leverage point
for health system strengthening [38].

Soft systems methodology offers one concrete approach to local level learn-
ing and trust-building, and can be supported by other actions to generate
trust. All such action also requires local leadership and engagement, and new
ways of managing local relationships. The range of leadership strategies needed
[48] include the ability to:

◆ Exercise authority through participation and negotiation, rather than
control and command. Leaders must establish fair and transparent
procedures that engage key stakeholders (political authorities, the
scientific community, health professionals, civil society, and citizens) in
the process of decision-making, generate legitimate decisions and contain
the influence of particular interest groups.

◆ Use a wide range of data and information in decision-making, going
beyond the statistics normally produced by health information systems
and identifying operational and systemic constraints. This information
must also be publicly accessible, flowing up the public bureaucracy
through open knowledge networks that involve field level experimentation
and adaptation, and learning-through-doing.

◆ Manage the political and implementation process actively, to secure high-
level political support and the other resources needed to initiate reforms,
and to bring about the changes in organizational structure and culture
that sustain implementation and limit resistance to change.

To strengthen health systems, new attention must now be paid to how to
develop these managerial leadership capacities, and enable the emergence of
organizational cultures and structures that support local level learning and
action.
