477 Breast cancer risk is influenced by rare coding variants in susceptibility genes such as BRCA1 and 478 many common, mainly non-coding variants. However, much of the genetic contribution to breast 479 cancer risk remains unknown. We report results from a genome-wide association study (GWAS) of 480 breast cancer in 122,977 cases and 105,974 controls of European ancestry and 14,068 cases and 481 13,104 controls of East Asian ancestry¹. We identified 65 new loci associated with overall breast 482 cancer at p<5x10⁸. The majority of credible risk SNPs in the new loci fall in distal regulatory 483 elements, and by integrating in-silico data to predict target genes in breast cells at each locus, we 484 demonstrate a strong overlap between candidate target genes and somatic driver genes in breast 485 tumours. We also find that heritability of breast cancer due to all SNPs in regulatory features was 486 2-5-fold enriched relative to the genome-wide average, with strong enrichment for particular 487 transcription factor binding sites. These results provide further insight into genetic susceptibility to 488 breast cancer and will improve the utility of genetic risk scores for individualized screening and 489 prevention.

490

492 We genotyped 61,282 female breast cancer cases and 45,494 female controls of European ancestry 493 with the OncoArray¹. Subjects came from 68 studies collaborating in the Breast Cancer Association 494 Consortium (BCAC) and Discovery, Biology and Risk of Inherited Variants in Breast Cancer 495 Consortium (DRIVE) (Supplementary Table 1). Using the 1000 Genomes Project (Phase 3) reference 496 panel, we imputed genotypes for ~21M variants. After filtering on minor allele frequency 497 (MAF)>0.5% and imputation quality score>0.3 (see Online Methods), we assessed the association 498 between breast cancer risk and 11.8M SNPs adjusting for country and ancestry-informative principal 499 components. We combined these results with results from the iCOGS project (46,785 cases and 500 42,892 controls)² and 11 other breast cancer GWAS (14,910 cases, 17,588 controls), using a fixed-501 effect meta-analysis.

502

503 Of 102 loci previously associated with breast cancer in Europeans, 49 showed evidence for 504 association with overall breast cancer in the OncoArray dataset at $P < 5 \times 10^{-8}$ and 94 at P < 0.05. Five 505 additional loci previously shown to be associated with breast cancer in Asian women also showed evidence in the European ancestry OncoArray dataset (P<0.01; Supplementary Tables 2-4)³⁻⁵. We 506 507 also assessed the association with breast cancer in Asians including 7,799 cases and 6,480 controls 508 from the OncoArray project and 6,269 cases and 6,624 controls from iCOGS. Of the 94 loci previously 509 identified in Europeans that were polymorphic in Asians, 50 showed evidence of association 510 (P<0.05). For the remaining 44, none showed a significant difference in the estimated odds ratio 511 (OR) for overall breast cancer between Europeans and Asians (P>0.01; Supplementary Table 5). The 512 correlation in effect sizes for all known loci between Europeans and Asians was 0.83, suggesting that 513 the majority of known susceptibility loci are shared between these populations.

514

515 To search for additional susceptibility loci, we assessed all SNPs excluding those within 500kb of a 516 known susceptibility SNPs (Figure 1). This identified 5,969 variants in 65 regions that were associated with overall breast cancer risk at $P < 5 \times 10^8$ (Table 1, Supplementary Tables 6-7). For two loci (lead 517 SNPs rs58847541 and rs12628403), there was evidence of a second association signal after 518 adjustment for the primary signal (rs13279803: conditional $P=1.6x10^{-10}$; rs373038216: $P=2.9x10^{-11}$; 519 520 Supplementary Table 8). Of the 65 new loci, 21 showed a differential association by ER-status 521 (P<0.05) with all but two (rs6725517 and rs6569648) more strongly associated with ER-positive 522 disease (Supplementary Tables 9-10). Forty-four loci showed evidence of association for ER-negative 523 breast cancer (P<0.05). Of the 51 novel loci that were polymorphic in Asians, nine were associated at 524 P<0.05 and only two showed a difference in the estimated OR between Europeans and Asians 525 (P<0.01; Supplementary Table 11).

526 To define a set of credible risk variants (CRVs) at the new loci, we first selected variants with P-values 527 within two orders of magnitude of the most significant SNPs in each region. Across the 65 novel 528 regions, we identified 2,221 CRVs (Supplementary Table 12), while the previous 77 identified loci 529 contained 2,232 CRVs (Online methods; Supplementary Table 13). We examined the evidence for 530 enrichment in these CRVs of 67 genomic features, including histone marks and transcription factor 531 binding sites (TFBS) in three breast cancer cell lines (Online Methods; Supplementary Tables 14-15; 532 **Extended Data Fig. 1**). Thirteen features were significant predictors of CRVs at $P<10^{-4}$; the strongest being DNAse I hypersensitivity sites in CTCF silenced MCF7 cells (OR 2.38, P=4.6x10⁻¹⁴). Strong 533 534 associations were also observed with binding sites for FOXA1, ESR1, GATA3, E2F1 and TCF7L2. Seven 535 of the 65 novel loci included only a single CRV (Supplementary Table 6), of which two are non-536 synonymous. SNP rs16991615 is a missense variant (p.Glu341Lys) in MCM8, involved in genome replication and associated with age at natural menopause and impaired DNA repair⁶. SNP 537 538 rs35383942 is a missense variant (p.Arg28Gln) in PHLDA3, encoding a p53-regulated repressor of 539 AKT^{7} .

540

541 We annotated each CRV with publicly available genomic data from breast cells in order to highlight 542 potentially functional variants, predict target genes and prioritise future experimental validation 543 (Supplementary Tables 6 and 12 with UCSC browser links). We developed a heuristic scoring system 544 based on breast-specific genomic data (integrated expression quantitative trait and in silico 545 prediction of GWAS targets - INQUISIT) to rank the target genes at each locus (Supplementary Table 546 **16).** Target genes were predicted by combining risk SNP data with multiple sources of genomic 547 information, including chromatin interactions (ChIA-PET and Hi-C), computational enhancer-548 promoter correlations (PreSTIGE, IM-PET, FANTOM5 and Super-enhancers), breast tissue-specific 549 eQTL results, TF binding (ENCODE ChIP-seq), gene expression (ENCODE RNA-seq) and topologically-550 associated domain (TAD) boundaries (Online Methods and Supplementary Tables 17-19). Target 551 gene predictions could be made for 58/65 new and 70/77 previously identified loci. Among 689 552 protein-coding genes predicted by INQUISIT, we found strong enrichment for established breast cancer drivers identified through tumour sequencing (20/147 genes, $P < 10^{-6})^{8-11}$, which increased 553 with increasing INQUISIT score (P=1.8x10⁻⁶). We compared INQUISIT with a) an alternative published 554 555 method (DEPICT, which predicts targets based on shared gene functions between potential targets at other associated loci)¹² which showed a weaker enrichment of breast cancer driver genes (P=0.06 556 557 after adjusting for the nearest gene, P=0.74 after adjusting for INQUIST score, and b) assigning the 558 association signal to the nearest gene, which showed only a weak enrichment of driver genes after 559 adjusting for the INQUISIT score (P=0.01; Extended Data Table 1 and Supplementary Table 20). Notably, most of the 689 putative target genes have no reported involvement in breast
tumorigenesis and some may represent additional genes influencing susceptibility to breast cancer.
However, functional assays will be required to confirm any of these candidates as risk genes.

563

Having used INQUISIT to predict target genes, we performed pathway gene set enrichment analysis (GSEA), visually summarized as enrichment maps (**Extended Data Fig. 2; Supplementary Tables 21-22**)¹³. Several growth or development related pathways were enriched, notably the fibroblast growth factor, platelet derived growth factor and Wnt signalling pathways¹⁴⁻¹⁶. Other cancer-related themes included ERK1/2 cascade, immune-response pathways including interferon signalling, and cell-cycle pathways. Pathways not found in earlier breast cancer GWAS include nitric oxide biosynthesis, AP-1 transcription factor and NF-kB (**Supplementary Table 23**).

571

572 To explore more globally the genomic features contributing to breast cancer risk, we estimated the proportion of genome-wide SNP heritability attributable to 53 publicly available annotations¹⁷. We 573 observed the largest enrichment in heritability (5.2-fold, $P=8.5 \times 10^{-5}$) for TFBS, followed by a 4-fold 574 575 (P=0.0006) enrichment for histone marker H3K4me3 (marking promoters). In contrast, we observed 576 a significant depletion (0.27, P=0.0007) for repressed regions (Supplementary Table 24). We 577 conducted cell type-specific enrichment analysis for four histone marks and observed significant 578 enrichments in several tissue types (Figure 2; Extended Data Figs. 3-7; Supplementary Table 25-26), including a 6.7-fold enrichment for H3K4me1 in breast myoepithelial tissue ($P=7.9 \times 10^{-5}$). We 579 580 compared the cell type-specific enrichments for overall, ER-positive and ER-negative breast cancer to 581 the enrichments for 16 other complex traits (Extended Data Figs. 3-7). Breast cancer showed 582 enrichment for adipose and epithelial cell types (including breast epithelial cells). In contrast, 583 psychiatric diseases showed enrichment specific to central-nervous-system cell types and 584 autoimmune disorders showed enrichment for immune cells.

585

586 We selected for further evaluation four loci to represent those predicted to act through proximal regulation (1p36 and 11p15) and distal regulation (1p34 and 7q22), because they had a relatively 587 small number of CRVs. The only CRV at 1p36, rs2992756 ($P=1.6 \times 10^{-15}$), is located 84bp from the 588 transcription start site of KLHDC7A. Of the 19 CRVs at 11p15 (smallest $P=1.4\times10^{-12}$), five were located 589 590 in the proximal promoter of PIDD1, implicated in DNA-damage-induced apoptosis and tumorigenesis¹⁸. INQUIST predicted KLHDC7A and PIDD1 to be target genes and they received the 591 592 highest score for likelihood of promoter regulation (Supplementary Table 18). Using reporter assays, 593 we showed that the KLHDC7A promoter construct containing the risk T-allele of rs2992756 has significantly lower activity than the reference construct, while the *PIDD1* promoter construct
 containing the risk haplotype significantly increased *PIDD1* promoter activity (Extended Data Fig. 8).

The 1p34 locus included four CRVs (smallest *P*=9.1x10⁻⁹) that fall within two putative regulatory elements (PREs) and are predicted by INQUISIT to regulate *CITED4* (PREs; **Extended Data Fig. 8**). CITED4 encodes a transcriptional coactivator that interacts with CBP/p300 and TFAP2 and can inhibit hypoxia-activated transcription in cancer cells¹⁹. Chromatin conformation capture (3C) assays confirmed that the PREs physically interacted with the *CITED4* promoter (**Extended Data Fig. 8**). Subsequent reporter assays showed that the PRE1 reference construct reduced *CITED4* promoter activity, whereas the risk *T*-allele of SNP rs4233486 located in PRE1 negates this effect.

604

Finally, the 7022 risk locus contained six CRVs (smallest $P=5.1 \times 10^{-12}$) which lie in several PREs 605 606 spanning ~40kb of CUX1 intron 1. Chromatin interactions were identified between a PRE1 607 (containing SNP rs6979850) and CUX1/RASA4 promoters and a PRE2 (containing SNP rs71559437) 608 and RASA4/PRKRIP1 promoters (Extended Data Fig. 9). Allele-specific 3C in heterozygous MBA-MB-609 231 cells showed that the risk haplotype was associated with chromatin looping, suggesting that the 610 protective allele abrogates looping between the PREs and target genes (Extended Data Fig. 9). These 611 results identify two mechanisms by which CRVs may impact target gene expression: through 612 transactivation of a specific promoter and by affecting chromatin looping between regulatory 613 elements and their target genes. These data provide in vitro evidence of target identification and 614 regulation, however further studies that include genome editing, oncogenic assays and/or animal 615 models will be required to fully elucidate disease-related gene function.

616

617 We estimate that the newly identified susceptibility loci explain ~4% of the two-fold familial relative 618 risk (FRR) of breast cancer and that in total, common susceptibility variants identified through GWAS 619 explain 18% of the FRR. Further, we estimate that variants imputable from the OncoArray, under a 620 log-additive model (see Online Methods), explain ~41% of the FRR, and thus, the identified 621 susceptibility SNPs account for \sim 44% (18%/41%) of the FRR that can be explained by all imputable 622 SNPs. The identified SNPs will be incorporated into risk prediction models, which can be used to 623 improve the identification of women at high and low risk of breast cancer: for example, using a 624 polygenic risk score based on the variants identified to date, women in the highest 1% of the 625 distribution have a 3.5-fold greater breast cancer risk than the population average. Such risk 626 prediction can inform targeted early detection and prevention.

628

629 ¹ The most significant variant at each locus is shown.

630 ² Chromosome

- 631 ³ Build 37 position
- 632 ⁴ Major/minor allele (forward strand)
- 633 ⁵ Minor allele frequency in controls in OncoArray dataset
- 634 ⁶ Per-allele odds ratio (95% confidence limits)
- 635 ⁷ *P*-value (see Online Methods)
- 636 ⁸ Genes within 2kb
- 637 ⁹ 21 base-pair deletion
- 638 ¹⁰ 36 base-pair deletion
- 639
- 640
- 641
- 642
- 643

644 Figure Legends

- **Figure 1. (a)** Manhattan plot showing log₁₀*P*-values for SNP associations with overall breast cancer
- 646 (b) Manhattan plot after excluding previously identified associated regions. The red line denotes
- 647 "genome-wide" significance ($P < 5 \times 10^{-8}$); the blue line denotes $P < 10^{-5}$.

695 Online Methods

696 Details of the studies and genotype calling and quality control (QC) for the iCOGS and eleven other GWAS are described elsewhere^{2,20}. Seventy-eight studies participated in the breast cancer 697 component of the OncoArray, of which 67 studies contributed European ancestry data and 12 698 699 contributed Asian ancestry data (one study, NBCS, was excluded as there were no controls from 700 Norway) (Supplementary Table 1). The majority of studies were population-based case-control 701 studies, or case-control studies nested within population-based cohorts, but a subset of studies 702 oversampled cases with a family history of the disease. All studies provided core data on disease 703 status and age at diagnosis/observation, and the majority provided additional data on clinico-704 pathological factors and lifestyle factors, which have been curated and incorporated into the BCAC 705 database (version 6). All participating studies were approved by their appropriate ethics review 706 board and all subjects provided informed consent.

707 OncoArray SNP Selection

708 Approximately 50% of the SNPs for the OncoArray were selected as a "GWAS backbone" (Illumina 709 HumanCore), which aimed to provide high coverage for the majority of common variants through 710 imputation. The remaining SNPs were selected from lists supplied by each of six disease-based 711 consortia, together with a seventh list of SNPs of interest to multiple disease-focused groups. 712 Approximately 72k SNPs were selected specifically for their relevance to breast cancer. These 713 included: (a) SNPs showing evidence of association from previous genotype data, based on a 714 combined analysis of eleven existing GWAS together the data from the iCOGS experiment; (b) SNPs 715 showing evidence of association with ER-negative disease (through a combined analysis with the 716 CIMBA consortium), triple negative disease, breast cancer diagnosed before age 40 years, high grade 717 disease, node positive disease or ductal carcinoma-in-situ; (c) SNPs potentially associated with 718 breast cancer survival; (d) SNPs selected for fine-mapping of 55 regions showing evidence of breast 719 cancer association at genome-wide significance; (e) rare variants showing evidence of association 720 through exome sequencing in multiple case families, whole-genome sequencing in high-risk cases 721 (DRIVE), or analysis of the ExomeChip (BCAC); (f) specific follow-up of regions of interest from breast 722 cancer GWAS in Asian, Latina and African/African-American women; (g) SNPs associated with breast 723 density, selected from GWAS conducted by the MODE consortium; (h) breast tissue-specific eQTLs (i) 724 lists of functional candidates from >30 groups. Lists were merged with lists from the other consortia 725 as described elsewhere¹.

726 OncoArray Calling and QC

727 Of the 568,712 variants selected for genotyping, 533,631 were successfully manufactured on the 728 array (including 778 duplicate probes). Genotyping for the breast cancer component of the 729 OncoArray, which included 152,492 samples, was conducted at six sites. Details of the genotyping 730 calling for the OncoArray are described in more detail elsewhere¹. Briefly, we developed a single 731 calling pipeline that was applied to more than 500,000 samples. An initial cluster file was generated 732 using data from 56,284 samples, selected to cover all the major genotyping centres and ethnicities, 733 using the Gentrain2 algorithm. Variants likely to have problematic clusters were selected for manual 734 inspection using the following criteria: call rate below 99%, variants with minor allele frequency 735 (MAF)<0.001, poor Illumina intensity and clustering metrics, or deviation from the expected 736 frequency as observed in the 1000 Genomes Project. This resulted in manual adjustment of the 737 cluster file for 3,964 variants, and the exclusion of 16,526 variants. The final cluster file was then 738 applied to the full dataset.

739 We excluded probable duplicates and close relatives within each study, and probable duplicates 740 across studies. We excluded samples with a call rate <95% or samples with extreme heterozygosity 741 (4.89 SD from the mean for the ethnicity). Ancestry was computed using a principal component 742 analysis, applied to the full OncoArray dataset, using 2318 informative markers on a subset of 743 \sim 47,000 samples. The analysis presented here was restricted to women of European ancestry, 744 defined as individuals with an estimated proportion of European ancestry >0.8, and women of East 745 Asian ancestry (estimated proportion of Asian ancestry >0.4), with reference to the HapMap (v2) 746 populations, based on the first two principal components. After quality control exclusions and 747 removing overlaps with the previous iCOGS and GWAS genotyping used in the analysis, the final 748 dataset comprised data from 61,282 cases and 45,494 of European ancestry 7,799 cases and 6,480 749 controls of Asian ancestry.

We excluded SNPs with a call rate <95% in any consortium, SNPs not in Hardy-Weinberg equilibrium 750 751 $(P < 10^{-7} \text{ in controls or } P < 10^{-12} \text{ in cases})$ and SNPs with concordance <98% among 5,280 duplicate 752 sample pairs. For the imputation, we additionally excluded SNPs with a MAF<1% and a call rate <98% 753 in any consortium, SNPs that could not be linked to the 1000 Genomes Project reference or differed significantly in frequency from the 1000 Genomes Project dataset (using the criterion 754 $\frac{(p_1 - p_0)^2}{((p_1 + p_0)(2 - p_1 - p_0))} > 0.007$, where p_0 and p_1 are the MAFs in the 1000 Genomes Project and 755 OncoArray European datasets, respectively). A further 1,128 SNPs where the cluster plot was judged 756 757 to be not ideal on visual inspection were excluded. Of the 533,631 SNPs that were manufactured on 758 the array, 494,763 SNPs passed the initial QC and 469,364 SNPs were used in the imputation.

759 Genotype Imputation

760 All samples were imputed using the October 2014 (version 3) release of the 1000 Genomes Project 761 dataset as the reference panel and number of sampled haplotypes per individual (Nhap)=800. The 762 iCOGS, OncoArray and nine of the GWAS datasets were imputed using a two-stage imputation 763 approach, using SHAPEIT2 for phasing and IMPUTEv2 for imputation^{21,22}. The imputation was 764 performed in 5Mb non-overlapping intervals. The subjects were split into subsets of ~10,000 765 samples; where possible subjects from the same study were included in the same subset. The BPC3 766 and EBCG studies were imputed separately using MACH and Minimac^{23,24}. 99.6% of SNPs with frequency >1% were imputable with r^2 >0.3 in the OncoArray dataset and 99.1% in the iCOGS 767 768 dataset. We generated estimated genotypes for all SNPs that were polymorphic (MAF>0.1%) in 769 either European or Asian samples (~21M SNPs). For the current analysis, however, we restricted to 770 SNPs with MAF>0.5% in the European OncoArray dataset (11.8M SNPs). One-step imputation 771 (without pre-phasing) was performed, on the iCOGS and OncoArray datasets, as a quality control 772 step for those associated loci where the imputation quality score was <0.9. Imputation quality for 773 the lead variants, as assessed by the IMPUTE2 quality score in the OncoArray dataset, was >0.80 for 774 all but one locus (Supplementary Table 27) rs72749841, quality score=0.65).

775

776 Principal Components Analysis

777 To adjust for potential (intra-continental) population stratification in the OncoArray dataset, 778 principal components analysis was performed using data from 33,661 uncorrelated SNPs (which 779 included 2,318 SNPs specifically selected on informativeness for determining continental ancestry) 780 with a MAF of at least 0.05 and maximum correlation of 0.1 in the OncoArray dataset, using 781 purpose-written software (http://ccge.medschl.cam.ac.uk/software/pccalc). For the main analyses, 782 we used the first ten principal components, as additional components did not further reduce 783 inflation in the test statistics. We used nine principal components for the iCOGS and up to ten 784 principal components for the other GWAS, where this was found to reduce inflation.

785 Statistical Analyses

Per-allele ORs and standard errors were generated for the OncoArray, iCOGS and each GWAS, adjusting for principal components using logistic regression. The OncoArray and iCOGS analyses were additionally adjusted for country and study, respectively. For the OncoArray analysis, we adjusted for country and 10 principal components. Adjustment for country rather than study was used to improve power since some studies had no few or no controls. We evaluated the adequacy of this approach by comparing the inflation in the test statistic with that obtained in corresponding 792 analysis in which we adjusted for study – the inflation was very similar (λ =1.15 vs. 1.17, based on the 793 backbone SNPs, equivalent to λ_{1000} =1.003, for a study of 1,000 cases and 1,000 controls, in both 794 cases). As an additional sensitivity analysis, we computed the effect sizes for the 65 novel loci 795 adjusting for study – the effect sizes were essentially identical to those presented. Estimates were derived using ProbAbel for the BPC3 and EBCG studies²⁵, SNPTEST for the remaining GWAS and 796 797 purpose written software for the iCOGS and OncoArray datasets. OR estimates and standard errors 798 were combined in a fixed effects inverse variance meta-analysis using METAL²⁶, adjusting the GWAS (but not iCOGS or OncoArray) results for genomic control as described previously². For the GWAS, 799 800 results were included in the analysis for all SNPs with MAF>0.01 and imputation r²>0.3. For iCOGS 801 and OncoArray we included all SNPs with $r^2 >= 0.3$ and MAF>0.005 (11.8M SNPs in total). We viewed 802 the primary tests of association as those based on all the meta-analysis over all stages, as this has been shown to be powerful than tests based on a test-replication approach²⁷. Eight sets of variants 803 were associated with breast cancer at $P < 5 \times 10^{-8}$ but were close to previous susceptibility regions, and 804 805 these became non-significant after adjustment for the previously identified lead variant. Two SNPs 806 on 22q13.2, rs141447235 and rs73161324, were both associated with overall breast cancer but, despite lying >500kb apart, were strongly correlated with each other (r^2 =0.50) and hence were 807 808 considered as a single novel signal.

809

810 For SNPs showing evidence of association, we additionally computed genotype-specific ORs for the 811 iCOGS and OncoArray dataset, and per-allele ORs for ER-negative and ER-positive disease. 812 Departures from a log-additive model were evaluated using a one degree of freedom likelihood ratio 813 test, comparing the log-additive model (genotypes parametrised as the number of rare alleles 814 carried) with the general model estimating ORs for each genotype. The genotype-specific risks for all 815 variants were consistent with a log-additive model (P>0.01; Supplementary Table 28). Tests for 816 differences in the OR by ER-status were derived using case-only analyses, in which estimates were 817 derived by logistic regression separately in the iCOGS and OncoArray datasets, adjusted as before, and then combined in a fixed-effects meta-analysis. These analyses were performed in R²⁸. 818

We assessed heterogeneity in the OR estimates among studies within each of the OncoArray, iCOGS and GWAS components, and between the (combined) estimates for the three components, using both the I² statistic and the *P*-value for Cochran's Q statistic (**Supplementary Table 27**). There was no evidence of heterogeneity among studies in the ORs for any of the loci in the OncoArray, but three loci showed some evidence of heterogeneity in the ORs among the GWAS, iCOGS and OncoArray datasets. To determine whether there were multiple independent signals in a given region, we performed multiple logistic regression analysis using SNPs within 500kb of each lead SNP, adjusting for the lead SNP. We used the genotypes derived by one-step imputation, performed the analyses separately in the iCOGS and Oncoarray datasets and combined the results (adjusted effect sizes and standard errors) using a fixed effects meta-analysis. For one of the two loci for which there was an additional signal significant at $P < 5 \times 10^{-8}$, the lead SNP from the one-step imputation differed from the lead SNP in the overall analysis, but was strongly correlated with it (**Supplementary Table 8**).

832

833 Definition of Known Hits

834 We attempted to identify all associations previously reported from genome-wide or candidate analysis at a significance level P<5x10⁻⁸ for overall breast cancer, ER-negative or ER-positive breast 835 836 cancer, in BRCA1 or BRCA2 carriers, or in meta-analyses of these categories. Where multiple studies 837 reported associations in the same region, we used the first reported association unless later studies 838 identified a variant that was clearly more strongly associated. We only included one SNP per 500kb 839 interval, unless joint analysis provided clear evidence ($P < 5 \times 10^{-8}$) of more than one independent 840 signal. For the analysis of credible risk variants (CRVs), we restricted attention to regions where the most significant signal had a P-value<10⁻⁷ in Europeans (77 regions). To avoid complications with 841 842 defining CRVs for secondary signals, we considered only the primary signal and defined CRVs as 843 those whose P-value was within two orders of magnitude of the most significant P-value.

844 In-Silico Analysis of CRVs

845 We combined multiple sources of in silico functional annotation from public databases to help 846 identify potential functional SNPs and target genes. To investigate functional elements enriched 847 across the region encompassing the strongest CRVs, we analysed chromatin biofeatures data from the Encyclopedia of DNA Elements (ENCODE) Project²⁹, Roadmap Epigenomics Projects³⁰ and other 848 849 data obtained through the National Center for Biotechnology Information (NCBI) Gene Expression 850 Omnibus (GEO) namely: Chromatin State Segmentation by Hidden Markov Models (chromHMM), 851 DNase I hypersensitive and histone modifications of epigenetic markers H3K4, H3K9, and H3K27 in 852 Human Mammary Epithelial (HMEC) and myoepithelial (MYO) cells, T47D and MCF7 breast cancer 853 cells and TF ChIP-seq in a range of breast cell lines (Supplementary Table 12).

854 Association of Genomic Features with CRVs

855 We first defined credible candidate variants as those located within 500kb of the most significant 856 SNP in each region, and with P-values within two orders of magnitude of the most significant SNPs. 857 This is approximately equivalent to flagging variants whose posterior probability of causality is within two orders of magnitude of that of the most significant SNP^{31,32}. We then selected 800 random 1Mb 858 859 control regions separated by at least 1Mb from each other and from the intervals defined by the 860 associated SNPs. The association with each feature was then evaluated using logistic regression, with 861 being a CRV as the outcome, and adjusting for the dependence due to linkage disequilibrium using 862 robust variance estimation, clustering on region, using the R package multiwayvcov.

863 *eQTL analyses*

864 Expression QTL analyses were performed using data from The Cancer Genome Atlas (TCGA) and Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) projects^{9,33}. The TCGA 865 866 eQTL analysis was based on 458 breast tumours that had matched gene expression, copy number, 867 and methylation profiles together with the corresponding germline genotypes available. All 458 868 individuals were of European ancestry as ascertained using the genotype data and the Local 869 Ancestry in adMixed Populations (LAMP) software package (LAMP estimate cut-off >95% 870 European)³⁴. Germline genotypes were imputed into the 1000 Genomes Project reference panel (October 2014 release) using IMPUTE2^{23,35}. Gene expression had been measured on the Illumina 871 HiSeq 2000 RNA-Seq platform (gene-level RSEM normalized counts³⁶), copy number estimates were 872 873 derived from the Affymetrix SNP 6.0 (somatic copy number alteration minus germline copy number variation called using the GISTIC2 algorithm³⁷), and methylation beta values measured on the 874 875 Illumina Infinium HumanMethylation450. Expression QTL analysis focused on all variants within 500 876 kb of the most significantly associated risk SNP in 142 genomic regions (each 2-Mb wide) containing 877 at least one previously identified or new overall breast cancer risk locus confirmed at genome-wide 878 significance in the current meta-analysis. Each variant was evaluated for its association with the 879 expression of every gene within 2 Mb that had been profiled for each of the three data types. The 880 effects of tumour copy number and methylation on gene expression were first regressed out using a method described previously³⁸. eQTL analysis was performed by linear regression, with residual gene 881 882 expression as outcome, germline SNP genotype dosage as the covariate of interest and ESR1 883 expression and age as additional covariates, using the R package Matrix eQTL³⁹.

The METABRIC eQTL analysis was based on 138 normal breast tissue samples resected from breast cancer patients of European ancestry. Germline genotyping for the METABRIC study was also done on the Affymetrix SNP 6.0 array, and gene expression in the METABRIC study was measured using the Illumina HT12 microarray platform (probe-level estimates). No adjustment was implemented for somatic copy number and methylation status since we were evaluating eQTLs in normal breast
 tissue. All other steps were identical to the TCGA eQTL analysis described above.

890

891 INQUISIT

We developed a computational pipeline, <u>in</u>tegrated expression <u>qu</u>antitative trait and <u>in sil</u>ico prediction of GWAS <u>t</u>argets (INQUISIT), to interrogate publically available data for the prioritisation of candidate target genes.

895

Data used for INQUISIT: Chromatin interaction data from ENCODE ChIA-PET analysis in MCF-7 cells for RNApolII, ERalpha, and CTCF factors were downloaded using UCSC Table Browser⁴⁰. Hi-C data derived from HMECs were obtained from Rao *et al.*⁴¹, using "interaction loops" as defined in the publication. Data were reformatted to facilitate intersection of query SNPs using BEDTools "intersect"⁴². For all interactions, termini were intersected with promoters using GENCODE v19⁴³ Basic gene annotations, where we defined promoters as -1.0 kb - +0.1 kb surrounding a transcription start site.

903

Enhancer-target gene predictions by several computational algorithms were collected. Each of these
 datasets assigns genes to enhancers. We used all MCF-7 and HMEC enhancer predictions (low and
 high stringency) made by PreSTIGE⁴⁴, IM-PET enhancer-gene predictions in MCF-7, HMEC and
 HCC1954 cell lines⁴⁵. Enhancer-transcription start site (E-TSS) links were identified from the
 FANTOM5 Consortium were identified⁴⁶, and enhancers detected in mammary epithelial cells were
 intersected with E-TSS links. We also collected typical and super-enhancers in MCF-7, HMEC and
 HCC1954 cells defined by Hnisz *et al.*⁴⁷.

911

TF ChIP-seq peak data for ESR1, FOXA1, GATA3, TCF7L2 and E2F1 from MCF-7, T47D and MCF-10A cells were downloaded in narrowPeak format from ENCODE. H3K4me3 and H3K9ac (characteristic of promoters) histone modification ChIP-seq peak data for all breast cells were obtained from ENCODE and Roadmap Epigenomics Project. ChromHMM data for breast cell samples (HMEC and myoepithelial: E027, E028 and E119) were downloaded from Roadmap Epigenomics.

917

918 Expression QTL analyses were conducted as described above. In the interpretation of the eQTL 919 results for INQUISIT (and in general) we focused on the overlap between the CRVs (risk signal) and 920 the top eQTL variants for a given gene (eQTL signal). If the eQTL *P*-value for a CRV was the same as, 921 or within 1/100th of the eQTL *P*-value of the SNP most significantly associated with expression of a

particular gene, that gene and the corresponding CRV were assigned a point for being an eQTL inINQUISIT.

924

Topologically-associated domain (TAD) boundaries were derived from Hi-C data⁴¹. Genomic intervals corresponding to "contact domains" from eight human cell types were merged using BEDTools "merge" resulting in annotation of regions most likely to encompass TAD units. Inter-TAD boundaries were identified using BEDTools "complement".

929

Gene level RNA-seq expression data generated under multiple experimental conditions in MCF-7 and
 normal mammary epithelial cells were downloaded from ENCODE. The FPKM (Fragments Per
 Kilobase of exon per Million fragments Mapped) values for each gene were extracted using the
 metagene R package⁴⁸ and averaged across all experiments to give an approximation of expression
 in breast cells. Accession numbers are given in Supplementary Table 29.

935

936 INQUISIT pipeline

Candidate target genes were evaluated by assessing each CRV's potential impact on regulatory or
coding features. Scores categorised by 1) distal gene regulation, 2) proximal gene regulation, or 3)
impact on protein coding were calculated using the following criteria (see also Supplementary Table
16).

941

Genomic annotation data for target gene predictions (chromatin interaction and computational enhancer-promoter assignment), ChIP-seq, histone modification, and chromHMM were curated into a BED formatted database. We intersected the chromosomal positions of CRVs with each category of genomic annotation data using BEDTools "intersect" (minimum 1 bp overlap), resulting in annotation of SNP-gene pairs with presence or absence of multiple classes of genomic data. Each gene was scored using a custom R script on the basis of the following criteria:

948 For distally regulated genes, a candidate gene was given 2 points if a CRV fell in an element that 949 revealed long range ChIA-PET or Hi-C interactions with that gene's promoter. One point was 950 added to a gene's score in the case of enhancers predicted by computational methods to target 951 that gene (in addition to experimental interactions if also observed). If the distal elements 952 harbouring SNPs also overlapped enriched cistromic TF (ESR1, FOXA1, GATA3, TCF7L2, E2F1) 953 ChIP-seq peaks, an additional point was given when one SNP-Enhancer-ChIP-seq peak 954 intersection occurred, but two points when there were multiple TF binding sites overlapping SNPs 955 in distinct interactions or enhancers (see Supplementary Table 16 for details). One point was given to significant eSNP-eGENE pairs. Predicted distal target genes which were among the list of
breast cancer driver genes were up-weighted with a further point (except for the analysis of
driver gene enrichment). Information regarding TAD boundaries was used to down-weight genes:
genes which were separated from CRVs by a TAD boundary were down-weighted by multiplying
their scores by 0.05. Scores for genes exhibiting no expression in MCF7 or HMEC (mean FPKM =
0) were multiplied by 0.1. This resulted in scores for each candidate target gene ranging from 0 to
8.

Variants were treated as potentially affecting proximal promoter regulation if they resided
 between -1.0 and +0.1 kb surrounding a transcription start site. Additional points was awarded to
 genes when variants overlapped promoter H3K4me3 or H3K9ac histone modification peaks,
 intersected with ESR1, FOXA1, GATA3, TCF7L2 or E2F1 TF binding sites, were significant eSNP eGENE pairs, and if the gene was annotated as a breast cancer driver gene. Gene scores were
 down-weighted (by a factor of 0.1) if they lacked expression in MCF-7 or HMEC samples.
 Resultant scores ranged from 0 to 5.

970 Intragenic variants were evaluated for their potential to impact protein function using a range of in silico prediction tools (CADD⁴⁹, FATHMM⁵⁰, LRT⁵¹, MutationAssessor⁵², Mutation Taster 2⁵³, 971 PolyPhen-2⁵⁴, PROVEAN⁵⁵ and SIFT⁵⁶ for missense variants; Human Splicing Finder⁵⁷ and 972 MaxEntScan⁵⁸ for splice variants). We scored genes with missense and nonsense variants 973 974 predicted to be functionally deleterious, and points for genes harbouring variants predicted to 975 alter splicing. Genes could therefore carry SNPs which affect coding and splicing and receive 976 increased scores. Additional points were given to genes which were breast cancer driver genes. 977 We multiplied scores by 0.1 when genes showed a lack of expression in breast cells. Possible 978 coding scores ranged from 0-4.

979

980 Enrichment of Somatic Breast Cancer Driver Genes in INQUISIT Target Gene Predictions

981 We listed 147 unique protein coding driver genes for breast cancer identified from four recent 982 tumour genome and exome sequencing studies (considering ZNF703 and FGFR1 as independent genes; **Supplementary Table 30**)⁸⁻¹¹. First, we examined overlap between this list of 147 genes and 983 984 the total set of unique target genes predicted by INQUISIT (n = 689) by one or more of the three 985 regulatory mechanisms (distal, promoter, and coding). The significance of this overlap was assessed 986 by randomly drawing (without replacement) 689 genes from the set of all protein coding genes 987 (GENCODE release 19, n = 20,243) one million times and calculating the probability of observing the 988 same (or stronger) overlap with the list of 147 drivers. Second, we hypothesised that this enrichment 989 would be stronger with progressively higher INQUISIT scores. We categorised all 20,243 protein 990 coding genes into four levels based on their INQUIST scores (level 1: coding score 2, promoter score 991 3-4, distal score >4; level 2: coding 1, promoter 1-2, distal 1-4; level 3: any score >0 but <1; level 4: 992 score 0 i.e. not a predicted target). The gene nearest to a risk locus is frequently assigned as a candidate target gene in GWAS in the absence of additional functional analysis⁵⁹. We observed that 993 994 seven of the 147 drivers were among the genes nearest to a previously or newly identified breast 995 cancer risk locus. Therefore, we used logistic regression, including data for all target genes predicted 996 by INQUISIT, with driver status as outcome, and evaluated INQUISIT score level and nearest gene 997 status as potential predictors of driver status (Supplementary Table 20).

998

Lead SNPs at 142 breast cancer risk associated loci were used as input into DEPICT which was then
 run using the default settings¹². We examined the relative performance of INQUISIT and DEPICT in
 predicting driver gene status using logistic regression models as above (Supplementary Table 20),
 adding DEPICT prediction as a covariate.

1003 Chromatin Conformation Capture (3C)

1004 MCF7 (ATCC #HTB22) and MDA-MB-231 (ATCC #HTB26) breast cancer cell lines were grown in RPMI 1005 medium with 10% FCS and antibiotics. Bre-80 normal breast epithelial cells (provided as a gift from 1006 Roger Reddel, CMRI, Sydney) were grown in DMEM/F12 medium with 5% horse serum (HS), 10 1007 µg/ml insulin, 0.5 µg/ml hydrocortisone, 20 ng/ml epidermal growth factor, 100 ng/ml cholera toxin 1008 and antibiotics. Cell lines were maintained under standard conditions, routinely tested for 1009 Mycoplasma and short tandem repeat (STR) profiled to confirm cell line identity. 3C libraries were 1010 generated using *Eco*RI as described previously⁶⁰. 3C interactions were quantitated by real-time PCR 1011 (qPCR) using primers designed within restriction fragments (Supplementary Table 31). qPCR was 1012 performed on a RotorGene 6000 using MyTaq HS DNA polymerase (Bioline) with the addition of 5 1013 mM of Syto9, annealing temperature of 66°C and extension of 30 sec. 3C analyses were performed 1014 in three independent 3C libraries from each cell line with each experiment quantified in duplicate. 1015 BAC clones covering each region were used to create artificial libraries of ligation products in order 1016 to normalize for PCR efficiency. Data were normalized to the signal from the BAC clone library and, 1017 between cell lines, by reference to a region within GAPDH. All qPCR products were electrophoresed 1018 on 2% agarose gels, gel purified and sequenced to verify the 3C product.

1019

1020 Plasmid Construction and Reporter Assays

1021 Promoter-driven luciferase reporter constructs were generated by insertion of PCR amplified 1022 fragments or synthesised gBlocks (Integrated DNA Technologies) containing the *KLHDC7A*, *PIDD1* or 1023 CITED4 promoters into the Kpnl/HindIII sites of pGL3-Basic. For the 1p34 locus, a 1169 bp putative 1024 regulatory element (PRE1) or 951 bp PRE2 were synthesised as gBlocks and cloned into the 1025 BamHI/Sall sites of the CITED4-promoter construct. The minor alleles of SNPs were introduced into 1026 promoter or PRE sequences by overlap extension PCR or gBlocks. Sequencing of all constructs 1027 confirmed variant incorporation (AGRF). MCF7 or Bre-80 cells were transfected with equimolar 1028 amounts of luciferase reporter plasmids and 50 ng of pRLTK transfection control plasmid with 1029 Lipofectamine 2000. The total amount of transfected DNA was kept constant at 600 ng for each 1030 construct by the addition of pUC19 as a carrier plasmid. Luciferase activity was measured 24 hr 1031 posttransfection by the Dual-Glo Luciferase Assay System. To correct for any differences in 1032 transfection efficiency or cell lysate preparation, *Firefly* luciferase activity was normalized to *Renilla* 1033 luciferase, and the activity of each construct was measured relative to the reference promoter 1034 constructs, which had a defined activity of 1. Statistical significance was tested by log transforming 1035 the data and performing 2-way ANOVA, followed by Dunnett's multiple comparisons test in 1036 GraphPad Prism.

1037

1038 Global Genomic Enrichment Analyses

1039 We performed stratified LD score regression analyses¹⁷ for overall breast cancer as well as stratified 1040 by ER status using the summary statistics based on the meta-analyses of the OncoArray, GWAS and 1041 iCOGS datasets. We restricted analysis to all SNPs present on the HapMap version 3 dataset that had 1042 a MAF > 1% and an imputation quality score R²>0.3 in the OncoArray data. LD scores were calculated 1043 using the 1000 Genomes Project Phase 3 EUR reference panel.

We first created a "full baseline model" as previously described that included 24 non-cell type specific publicly available annotations as well as 24 additional annotations that included a 500-bp window around each of the 24 main annotations¹⁷. Additionally, we also included 100-bp windows around ChIP-seq peaks as well as one annotation containing all SNPs leading to a total of 53 overlapping annotations.

We subsequently performed analyses using cell-type specific annotations for four histone marks H3K4me1, H3K4me3, H3K9ac and H3K27ac across 27-81 cell types depending on histone mark¹⁷. Each cell-type-specific annotation corresponded to a histone mark in a single cell type, and there were 220 such annotations in total. We augmented the baseline model by adding these annotations individually, creating 220 separate models, each with 54 annotations (53+1). This procedure controls for the overlap with the 53 functional categories in the full baseline model but not with the 219 other cell type specific annotations. 1056 We further tested the differences in functional enrichment between ER-positive and ER-negative 1057 subsets through a Wald test, using the regression coefficients and standard errors for the two 1058 subsets based on the models described above.

1059

1060 Contribution of Identified Variants to the Familial Relative Risk of Breast Cancer

1061 We estimated the proportion of the familial risk of breast cancer due to the identified variants, 1062 under a log-additive model, using the formula:

1063 $\sum_i p_i (1 - p_i)(\beta_i^2 - \tau_i^2)/\ln(\lambda))$, where p_i is the MAF for variant *i*, β_i is the log(OR) estimate for 1064 variant *i*, τ_i is the standard error of β_i and λ =2 is the assumed overall familial relative risk.

1065

1066 To compute the corresponding estimate for the FRR due to all variants, we wish to estimate 1067 $h_f^2 = \sum_i 2p_i(1-p_i)\beta_i^2$ where the sum is now over the all variants and θ_i is the true relative risk 1068 conferred by variant *i*, assuming a log-additive model. We refer to h_f^2 as the *frailty scale* heritability. 1069 We first obtained the estimated observed heritability based on the full set of summary estimates 1070 using LD Score Regression¹⁷ and then converted this to an estimate on the frailty scale using the 1071 $h_f^2 = \frac{h_{obs}^2}{P(1-P)}$, where *P* is the proportion of samples in the population that are cases.

1072

1073 Pathway Analyses

1074 The pathway gene set database (http://download.baderlab.org/EM Genesets, file Human_GOBP_AllPathways_no_GO_iea_April_01_2017_symbol.gmt)¹³ from the Bader lab dated 1075 April 1, 2017 was used in all analyses. This database contains pathways from Reactome⁶¹, NCI 1076 Pathway Interaction Database⁶², GO (Gene Ontology) biological process⁶³, HumanCyc⁶⁴, MSigdb⁶⁵, 1077 NetPath⁶⁶ and Panther⁶⁷. For GO, terms inferred from electronic annotation were excluded from our 1078 1079 analyses. The same pathway may be defined in two or more databases with potentially different sets 1080 of genes. All versions of such 'duplicate' pathways were included. To provide more biologically 1081 meaningful results and reduce false positives, only pathways that contained between 10 and 200 1082 genes were used. Pathway size was determined by the total number of genes in the pathway that 1083 could also be mapped to the genes included in the GWAS dataset (actual pathway size may be 1084 larger).

1085

1086 SNPs were assigned to genes using the INQUISIT target prediction method described above for all SNPs with P-value $< 5x10^{-2}$ (~1.25 million associations). This cutoff was chosen based on a threshold 1087 1088 analysis that showed that 19 of the 20 pathway themes found using all SNP associations (~16 million) 1089 and a simple distance-based SNP-to-gene mapping method could be recovered using this smaller subset of associations. More stringent cutoffs resulted in fewer themes being covered (e.g. three 1090 1091 themes found using SNPs with p-value $< 5x10^6$ or \sim 33K SNP associations). Gene significance was calculated by assigning the statistic of the most significant SNP among all SNPs assigned to a 1092 gene^{68,69}. Since histone genes contained a high number of mapped SNPs, we selected representative 1093 1094 SNP associations to avoid pathway enrichments based solely on the increased number of SNPs at 1095 these loci (i.e. chr6:27657944 for HIST1, chr1:149219841, for HIST2, chr1: 228517406 for HIST3, 1096 chr12: 14871747 for HIST4).

1097

The gene set enrichment analysis (GSEA) algorithm as implemented in the GenGen package⁶⁹ was 1098 used to perform pathway analysis. Wang et al.⁷⁰ modified the original GSEA algorithm to work with 1099 GWAS datasets, using SNP significance and SNP-to-gene mapping instead of gene expression data. 1100 1101 Briefly, the algorithm calculates an enrichment score (ES) for each pathway based on a weighted Kolmogorov-Smirnov statistic (refer to ⁷⁰ for more details). Pathways that have most of their genes 1102 at the top of the ranked list of genes obtain higher ES values. Note that only the largest positive ES 1103 1104 was considered as opposed to largest absolute ES (i.e. largest deviation from zero). This modification 1105 (recommended by the GenGen authors for GWAS analysis) was performed to include only pathways 1106 that are significantly affected between cases and controls and ignore those with significant negative 1107 ES values (this may happen if a pathway is significantly less altered than expected by chance). Only 1108 pathways containing greater than 10 genes with at least one of these genes with P-value $< 5 \times 10^{-8}$ 1109 were retained as higher confidence for subsequent analysis. These pathways, together with the 1110 genes reaching the significance threshold, are listed in **Supplementary Table 21**.

1111

The pathway analysis assigns an enrichment score (ES) value for each pathway. These values were normalized and p-values for each pathway were obtained by comparing them to null distributions for OncoArray and iCOGS data sets separately. The null distributions were computed by permuting case/control labels 1,000 times (keeping the number of cases and controls the same in each iteration) and recomputing all enrichment statistics. FDR values were computed using the statistics from the null distributions and all pathways with FDR < 0.05 in either OncoArray or iCOGS distributions were considered further. Pathway findings were further considered if they contained 1119 more than one significant gene and if they could be confirmed to be involved in breast cancer as reported in at least one of five published large-scale breast cancer GWAS⁷¹⁻⁷⁵ or reported elsewhere 1120 1121 in the literature. Further, themes that were weakly associated with breast cancer (based on a 1122 literature search) were only included if they had a FDR < 0.05 and at least four novel genes (i.e. was 1123 not found among the genes from mapped themes containing pathways known to be involved in breast cancer) (Extended Data Fig. 2). Pathways related to "sensory perception of smell" were 1124 1125 removed as there is no literature evidence for their involvement in breast cancer and because they 1126 contain genes close to each other on chromosome 6 which are frequently correlated.

1127

1128 An enrichment map was created using the Enrichment Map (EM) v 2.1.0 app^{13} in Cytoscape v 3.3⁷⁶.

1129 Pathways nodes were laid out using a force directed layout and nodes with gene set overlap of over

1130 0.55 were connected by edges. Related pathway nodes were manually clustered and labelled as

1131 themes.

1274

1273 Acknowledgements

1275 The authors wish to thank all the individuals who took part in these studies and all the 1276 researchers, clinicians, technicians and administrative staff who have enabled this work to be 1277 carried out.

1278 Genotyping of the OncoArray was principally funded from three sources: the PERSPECTIVE 1279 project, funded from the Government of Canada through Genome Canada and the Canadian 1280 Institutes of Health Research, the Ministère de l'Économie, de la Science et de l'Innovation du 1281 Québec through Genome Québec, and the Quebec Breast Cancer Foundation; the NCI Genetic 1282 Associations and Mechanisms in Oncology (GAME-ON) initiative and Discovery, Biology and 1283 Risk of Inherited Variants in Breast Cancer (DRIVE) project (NIH Grants U19 CA148065 and 1284 X01HG007492); and Cancer Research UK (C1287/A10118 and. C1287/A16563). BCAC is funded 1285 by Cancer Research UK [C1287/A16563], by the European Community's Seventh Framework 1286 Programme under grant agreement 223175 (HEALTH-F2-2009-223175) (COGS) and by the 1287 European Union's Horizon 2020 Research and Innovation Programme under grant agreements 1288 633784 (B-CAST) and 634935 (BRIDGES). Genotyping of the iCOGS array was funded by the 1289 European Union (HEALTH-F2-2009-223175), Cancer Research UK (C1287/A10710), the 1290 Canadian Institutes of Health Research for the "CIHR Team in Familial Risks of Breast Cancer" 1291 program, and the Ministry of Economic Development, Innovation and Export Trade of Quebec – 1292 grant # PSR-SIIRI-701. Combining the GWAS data was supported in part by The National 1293 Institute of Health (NIH) Cancer Post-Cancer GWAS initiative grant U19 CA 148065 (DRIVE, part 1294 of the GAME-ON initiative). For a full description of funding and acknowledgments, see 1295 Supplementary Note.

1297 Author Contributions

Writing Group: K.Michailidou, S.Lindström, J.Beesley, S.Hui, S.Kar, P.Soucy, S.L.E., G.D.B., G.C-T.,J.Simard, P.K., D.F.E.

1300 Conceived OncoArray and obtained financial support: C.I.A., J.Simard, P.K., D.F.E.

- 1301 Designed OncoArray: J.D., E.D., A.Lee, Z.W., A.C.A., S.J.C., P.K., D.F.E.
- 1302 Led COGS project: P.Hall.
- 1303 Led DRIVE project: D.J.H.
- 1304 Led PERSPECTIVE project: J.Simard.
- 1305 Led working groups of BCAC: A.C.A., I.L.A., P.D.P.P., J.Chang-Claude, R.L.M., M.G-C., M.K.S.,1306 A.M.D.
- 1307 Data management: J.D., M.K.B., Q.Wang, R.Keeman, U.E., S.B., J.Chang-Claude, M.K.S.
- 1308 Bioinformatics analysis: J.D., J.Beesley, A.Lemaçon, P.Soucy, J.A., M.Ghoussaini, J.Carroll, A.D.,

1309 A.E. McC R, S.R.L.

- 1310 Statistical analysis: K.Michailidou, S.Lindström, S.Hui, S.Kar, A.Rostamianfar, J.T., X.C., L.Fachal,
- 1311 X.J., H.Finucane, G.D.B., P.K., D.F.E.
- 1312 Functional analysis: D.G., X.C., J.Beesley, J.D.F., K.McCue, S.L.E., G.C-T.
- 1313 OncoArray Genotyping: M.A., F.B., C.Baynes, D.M.C., J.M.C., K.F.D., N.Hamel, B.H., K.J., C.L.,

1314 J.Meyer, E.P., J.R., G.S., D.C.T., D.V.D.B., D.V., J.V., L.X., B.Z., A.M.D.

1315 Provided DNA samples and/or phenotypic data: M.A.A., K.A., H.A-C., N.N.A., V.A., K.J.A., B.A., 1316 P.L.A., M.Barrdahl, M.W.B., J.Benitez, M.Bermisheva, L.Bernstein, C.Blomqvist, N.V.B., S.E.B., 1317 B.Bonanni, A-L.B-D., J.S.B., H.Brauch, P.Brennan, H.Brenner, L.Brinton, P.Broberg, I.W.B., A.B., 1318 A.B-W., S.Y.B., T.B., B.Burwinkel, K.B., H.Cai, Q.C., T.C., F.C., A.Carracedo, B.D.C., J.EstebanC., 1319 T.L.C., T-Y.D.C, K.S.C., J-Y.Choi, H.Christiansen, C.L.C., M.C., E.C-D., S.C., A.Cox, D.C., S.S.C., K.C., 1320 M.B.D., H.D., P.D., T.D., I.d.S.S., M.Dumont, L.D., M.Dwek, D.M.E., A.B.E., A.H.E., C.Ellberg, 1321 M.Elvira, C.Engel, M.Eriksson, P.A.F., J.F., D.F-J., O.F., H.Flyger, L.Fritschi, V.Gaborieau, M.G., M.G-D., Y-T.G., S.M.G., J.A.G-S., M.M.G., V.Georgoulias, G.G.G., G.G., M.S.G., D.E.G., A.G-N., 1322 1323 G.I.G., M.Grip, J.G., A.G., P.G., L.H., E.H., C.A.H., N.Håkansson, U.H., S.Hankinson, P.Harrington, 1324 S.N.H., J.M.H., M.H., A.Hein, J.H., P.Hillemanns, D.N.H., A.Hollestelle, M.J.H., R.N.H., J.L.H., M-F.H., C-N.H., G.H., K.H., J.I., H.Ito, M.I., H., A.J., W.J., E.M.J., N.J., M.J., A.J-V., R.Kaaks, M.K., K.K., 1325 1326 D.K., Y.K., M.J.K., S.Khan, E.K., J.I.K., S-W.K., J.A.K., V-M.K., V.N.K., U.K., A.K., D.L., L.L., C.N.L., E.L., 1327 J.W.L., M.L., F.L., J.Li, J.Lilyquist, A.Lindblom, J.Lissowska, W-Y.L., S.Loibl, J.Long,

1341 All authors read and approved the final version of the manuscript.

1342 Author Information. A subset of the data that support the findings of this study is publically 1343 available via dbGaP (www.ncbi.nlm.nih.gov/gap; accession number phs001265.v1.p1). The 1344 complete dataset will not be made publicly available due to restraints imposed by the ethics 1345 committees of individual studies; requests for data can be made to the corresponding author or 1346 the Data Access Coordination Committee (DACCs) of BCAC 1347 (http://bcac.ccge.medschl.cam.ac.uk/): BCAC DACC approval is required to access data from 1348 studies ABCFS, ABCS, ABCTB, BBCC, BBCS, BCEES, BCFR-NY, BCFR-PA, BCFR-UT, BCINIS, BSUCH, 1349 CBCS, CECILE, CGPS, CTS, DIETCOMPLYF, ESTHER, GC-HBOC, GENICA, GEPARSIXTO, GESBC, 1350 HABCS, HCSC, HEBCS, HMBCS, HUBCS, KARBAC, KBCP, LMBC, MABCS, MARIE, MBCSG, MCBCS, 1351 MISS, MMHS, MTLGEBCS, NC-BCFR, OFBCR, ORIGO, pKARMA, POSH, PREFACE, RBCS, SKKDKFZS, 1352 SUCCESSB, SUCCESSC, SZBCS, TNBCC, UCIBCS, UKBGS and UKOPS (see Supplementary Table 1).

Summary results for all variants are available at <u>http://bcac.ccge.medschl.cam.ac.uk/</u>. Requests for further data should be made through the BCAC Data Access Co-ordinating Committee (<u>http://bcac.ccge.medschl.cam.ac.uk/</u>). Reprints and permissions information is available through <u>www.nature.com/reprints</u>. The authors confirm that they have no competing financial interests. Correspondence should be addressed to D.F.E. (<u>dfe20@medschl.cam.ac.uk</u>).

1358

Extended Data Table 1: INQUISIT, DEPICT, and nearest gene as predictors of driver status. Scores converted into levels for analysis. For INQUISIT: level 1 (coding score of 2 OR promoter score of 3 or 4 OR distal score > 4), level 2 (coding score of 1 OR promoter of 1 or 2 OR distal score of 1, 2, 3, or 4), level 3 (coding/promoter/distal scores > 0 but < 1), and level 4 (not predicted to be a target gene by INQUISIT). For DEPICT: level 1 (DEPICT predicted target gene at $P \le 0.05$), level 2 (DEPICT predicted target gene but with P > 0.05), level 3 (not predicted to be a target gene by DEPICT).

1366

1367 Extended Data Figure 1: Global mapping of biofeatures across novel loci associated with 1368 overall breast cancer risk. The overlaps between potential genomic predictors in relevant breast 1369 cell lines and candidate causal risk variants (CRVs) within each locus. On the x-axis, each column 1370 represents a CRV (see **Online Methods**). The most significant SNPs are identified in each region. 1371 On the y-axis, biofeatures are grouped into five functional categories: genomic structure (red), 1372 enhancer marks (dark green), histone marks (blue), open chromatin marks (dark blue) and transcription factor binding sites (dark violet). Colored elements indicate SNPs for which the 1373 1374 feature is present. For data sources, see Online Methods ("In-Silico Analysis of CRVs").

1375

Extended Data Figure 2: Pathway enrichment map for susceptibility loci based on summary association statistics. Each circle (node) represents a pathway (gene set), coloured by enrichment score (ES) where redder nodes indicate lower FDRs. Larger nodes indicate pathways with more genes. Green lines connect pathways with overlapping genes (minimum overlap 0.55). Pathways are grouped by similarity and organized into major themes (large labelled circles).

1382

Extended Data Figure 3. Heatmap showing patterns of cell type-specific enrichments for breast tissue across three histone marks (H3K4me1, H3K4me3 and H3K9ac) for breast cancer overall, ER-positive breast cancer and ER-negative breast cancer as well as 16 other traits.

1386

Extended Data Figure 4: Heatmap showing patterns of cell type-specific enrichments for
 histone mark H3K27ac in breast cancer overall, ER+ and ER- breast cancer as well as 16
 other traits.

1390

Extended Data Figure 5: Heatmap showing patterns of cell type-specific enrichments for histone mark H3K4me1 in breast cancer overall, ER+ and ER- breast cancer as well as 16 other traits.

1394

Extended Data Figure 6: Heatmap showing patterns of cell type-specific enrichments for histone mark H3K4me3 in breast cancer overall, ER+ and ER- breast cancer as well as 16 other traits.

1398

Extended Data Figure 7: Heatmap showing patterns of cell type-specific enrichments for
 histone mark H3K9ac in breast cancer overall, ER-positive and ER-negative breast cancer
 as well as 16 other traits.

1402

1403 Extended Data Figure 8: Functional assessment of regulatory variants at 1p36, 11p15 and 1p34 1404 risk loci. a, The KLHDC7A or b, PIDD1 promoter regions containing the reference (prom-Ref) or 1405 risk alleles (prom-Hap), were cloned upstream of the pGL3 luciferase reporter gene. MCF7 or Bre-80 cells were transfected with constructs and assayed for luciferase activity after 24 h. Error 1406 1407 bars denote 95% CI (n=3). P-values were determined by two-way ANOVA followed by Dunnett's 1408 multiple comparisons test (*P<0.05, **P<0.01, ***P<0.001). **c**, 3C assays. A physical map of the 1409 region interrogated by 3C is shown first. Grey boxes depict the putative regulatory elements 1410 (PREs), blue vertical lines indicate the risk-associated SNPs and black dotted line represents 1411 chromatin looping. The graphs represent three independent 3C interaction profiles. 3C libraries 1412 were generated with EcoRI, grey vertical boxes indicate the interacting restriction fragment (containing PRE1 and PRE2). Error bars denote SD. d, PRE1 or PRE2 containing the reference 1413 1414 (PRE-ref) or risk (PRE-Hap) haplotypes were cloned downstream of a CITED4 promoter-driven 1415 luciferase construct (CITED4 prom). MCF7 or Bre-80 cells were transfected with constructs and 1416 assayed for luciferase activity after 24 h. Error bars denote 95% CI (n=3). P-values were 1417 determined by two-way ANOVA followed by Dunnett's multiple comparisons test (**P<0.01, ***P<0.001). 1418

1419

Extended Data Figure 9: Functional assessment of regulatory variants at the 7q22 risk locus. ae, 3C assays. A physical map of the region interrogated by 3C is shown first. Grey horizontal boxes depict the putative regulatory elements (PREs), blue vertical lines indicate the riskassociated SNPs and black dotted line represents chromatin looping. The graphs represent three independent 3C interaction profiles between the a, *CUX1*, b, d, *PRKRIP1* or c, e, *RASA4* promoter

- 1425 regions and PREs. 3C libraries were generated with *Eco*RI, grey vertical boxes indicate the
- 1426 interacting restriction fragment (containing PRE1 and/or PRE2). Error bars denote SD. f, g, Allele-
- 1427 specific 3C. 3C followed by Sanger sequencing for the f, PRKRIP1-PRE2 or g, RASA4-PRE1 or -
- 1428 PRE2 in heterozygous MDA-MB-231 breast cancer cells.
