KEYWORDS

acute stroke, antihypertensive drug, blood pressure, glyceryl trinitrate, randomised controlled trial, statistical analysis plan

1 INTRODUCTION

High blood pressure (BP) is present in 70% or more of patients with acute ischaemic stroke and spontaneous intracerebral haemorrhage (ICH).¹ Affected patients have a worse outcome, whether judged as early recurrence, death within a few weeks, or combined death and dependency after several months.¹⁻⁴ Lowering BP might therefore reduce these events and improve functional outcome providing that cerebral perfusion is not reduced in the presence of dysfunctional cerebral autoregulation. However, recent large trials have been inconclusive in their results.^{5,6}

Nitric oxide (NO) donors are candidate treatments for acute stroke; NO is a cerebral and systemic vasodilator, modulates vascular and neuronal function, and inhibits apoptosis.⁷ Preclinical studies of cerebral ischaemia have found that NO donors reduce stroke lesion size, and improve regional cerebral blood flow and functional outcome.⁸ Five small clinical studies of NO donors have been performed, these involving a total of 208 patients with recent stroke. Intravenous sodium nitroprusside reduced BP without altering CBF, and exhibited antiplatelet effects (thereby precluding its use in spontaneous ICH).⁹ Four pilot trials of transdermal glyceryl trinitrate (GTN) found that it lowered BP by approximately 8%; did not alter platelet function (and so could be given in ICH); did not alter middle cerebral artery blood flow velocity or regional cerebral blood flow; improved aortic vascular compliance; and could be given to patients with dysphagia.¹⁰⁻¹³ No safety concerns were present in these studies, and in one small trial ultra-acute treatment with GTN was associated with an improved functional outcome.^{13,14}

On the basis of this pre-clinical and clinical data showing feasibility, tolerability and apparent safety of GTN, and the potential for efficacy, the large 'Efficacy of Nitric Oxide in Stroke' (ENOS) trial was started and is ongoing. ENOS is assessing, in a partial factorial prospective randomised open blinded-outcome design, whether to lower BP with GTN (versus no GTN), and whether to continue (versus stop) pre-stroke antihypertensive therapy. The trial commenced in 2001 and its protocol was published in 2006.¹⁵ Several non treatment-related and blinded analyses of the ENOS database have been published since the start of the trial.¹⁶⁻²⁰ The independent Data Monitoring Committee have assessed the trial every 6 months and on each occasion recommended that the trial should continue.

2 PRIMARY RESEARCH QUESTIONS

1. Does transdermal glyceryl trinitrate (GTN, 5 mg daily for 7 days), when given acutely after stroke, reduce death or dependency at 90 days, as compared to no GTN. This question applies to all randomised patients.
2. Does continuing pre-stroke antihypertensive medications reduce death or dependency at 90 days, as compared to stopping these medications for 7 days. This question applies to those randomised patients who were taking antihypertensive medications immediately prior to stroke onset (anticipated to be ~50% of the whole trial population).

3 TRIAL DESIGN

3.1 Design

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

ENOS is an international multicentre prospective randomised single-blind blinded-endpoint controlled partial-factorial trial with centralised randomisation (stratification and minimisation) to ensure allocation concealment and reduce bias.

3.2 Trial population

Previously independent adult patients who are conscious, have residual limb weakness, have systolic blood pressure between 140-220 mmHg, and are within 48 hours of stroke onset, are eligible for enrolment. The full inclusion-exclusion criteria are given in the protocol.¹⁵

3.3 Randomisation

All patients are randomised to GTN vs no GTN. Those patients who are taking antihypertensive medications immediately prior to their stroke are also randomised to continue or stop this. As a result, there are 6 treatment groups, with a working sample size totalling 3,800 patients (which exceeds the grant-funded 3,500 patients), and approximately 50% of patients on BP drugs before their stroke.

	Pre-stroke	BP drugs	No pre-stroke BP drugs	Size by row
	Continue	Stop		
GTN	475	475	950	1,900
No GTN	475	475	950	1,900
Size by column	950	950	1,900	3,800

The process of randomisation includes (1) stratification; (2) minimisation; and then (3) simple randomisation. Stratification and minimisation allow for improved matching at baseline, stratification allows variable categories to be treated as trials in their own right, minimisation increases statistical power,²¹ and simple randomisation reduces predictability. The minimisation variables will be used for adjustment of the primary and secondary analyses.

3.3.1 Stratification

- i. Immediate prior use of antihypertensive treatment.
- ii. Stroke pathological type (ischaemic stroke [IS]/unknown, spontaneous intracerebral haemorrhage [ICH])
- iii. Country

3.3.2 Minimisation

- i. Age (≤ 70 years, > 70 years)
- ii. Sex (female, male)
- iii. History of hypertension (no, yes)
- iv. History of previous stroke (no, yes)
- v. Diabetes mellitus (no, yes)
- vi. Current use of nitrate therapy (no, yes)
- vii. Stroke severity (Scandinavian Stroke Scale,²² SSS > 30 , ≤ 30)
- viii. Total anterior circulation syndrome (no, yes)²³
- ix. Systolic BP (≤ 160 , > 160 mmHg)
- x. Treated with rt-PA prior to randomisation (yes, no)
- xi. Feeding status (other, iv fluids/nothing)
- xii. Time to randomisation (≥ 24 hours, < 24 hours)

3.3.3 Simple randomisation

On 5% of patients at time of minimisation.

3.4 Minimising bias

Multiple measures are taken to minimise bias: central data registration with real-time on-line validation; concealment of allocation; patient blinding to GTN (gauze dressing over GTN patch or equivalent area of skin); blinded central telephone assessment of 3 month outcome by staff at National Coordinating Centres; assessment of patient recall of treatment;¹¹ blinded adjudication of CT scans/SAEs; exclusion of patients enrolled in other trials; analysis by intention-to-treat; and adjustment for minimisation factors and non-randomised treatment (alteplase).

3.5 Ethics and regulatory approvals

ENOS is run according to the principles of the Declaration of Helsinki and 'Good Clinical Practice'. The trial was approved by national competent authorities (where applicable), e.g. European Medicines Agency (EudraCT number 2004-003870-27, date 1/10/2004), UK Medicines & Healthcare products Regulatory Authority (formerly Medicines Control Agency, reference MF8000/10820, date 16/2/2001); national and local research ethics committees (REC), e.g. UK Trent REC (reference MREC/01/4/046, date 3/9/2001), Scottish 1 REC (reference MREC/02/0/121, date 7/1/2003); and adopted by the Australian, Canadian, and UK NIHR Stroke Research Networks (date 25/4/2006). Trial funding from BUPA Foundation, and the Medical Research Council (grant: G0501797, awarded 26/4/2006) followed external peer review.

4 STATISTICAL ANALYSIS PLAN (SAP)

4.1 Original SAP

The trial was originally designed to recruit 5,000 patients so as to detect an absolute risk reduction in the binary outcome of death or dependence (modified Rankin Scale, mRS>2) of 5% from 50% in the control group to 45% in the GTN group, with power 90%, significance 5%, and allowance for losses to follow-up. The original planned method of analysis, as published in the protocol paper,¹⁵ was to compare the proportion of participants who were dead or dependent at 90 days between the treatment groups.

4.2 Revised SAP

Recent research has shown that binary analysis of the 7-level mRS is sub-optimal and that statistical power is increased by using all the data at each level by comparing differences in distribution across the whole scale between the treatment groups.²⁴ This approach is now recommended by the European Stroke Organisation.²⁵ A further, and additional, increase in statistical power is achieved by incorporating key prognostic baseline variables as covariates.²⁶ Other groups have presented similar findings and used this approach.²⁷⁻²⁹

Hence, the primary analysis of the mRS in ENOS will utilise the shift approach, as analysed using ordinal logistic regression, with adjustment for covariates, with comparison between treatment groups (GTN/no GTN; continue/stop pre-stroke BP medications). The overall proposal to change the method of analysis of the primary outcome from binary to ordinal was first presented to, and agreed by, the Trial Steering Committee in January 2008, and confirmed in 2009. An early draft version of this SAP, highlighting this change, was posted on the trial website in April 2009.

This change to the design of ENOS was made without knowledge of any interim analysis that split patients by treatment group. The statistician who prepares analyses for the independent Data Monitoring Committee (DMC), and the DMC themselves, were not

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

involved in the writing of this statistical analysis plan (SAP), and have not seen or commented on it.

4.3 Outcomes and their analysis

All outcomes will be assessed by:

- GTN versus no GTN
- Continue versus temporarily stop pre-stroke antihypertensive medication

4.3.1 Analysis populations

The following populations of patients are defined for analyses and take account that the trial is single-blind in design.

4.3.1.1 Intention-to-treat safety population

All randomised participants with vital status recorded.

4.3.1.2 Intention-to-treat efficacy population

All randomised participants with the primary outcome recorded.

4.3.1.3 Per protocol population

All randomised participants with the primary outcome recorded and who did not have a relevant protocol violation as defined in **Appendix B.2.8**. A key criterion is that an included patient must have received at least 4 days of treatment (or died before this).

4.3.1.4 Analyses by population

All efficacy analyses will be performed on the intention to treat population. A separate 'per protocol' analysis will be performed on the primary and key secondary outcomes. Safety analyses will be performed on the safety population.

4.3.2 Missing data, and death

Missing data will not be imputed. Participants who die will be assigned discrete values for outcome measures with a value worse than any living value (as is standard for mRS, BI). This avoids giving death the same value as the worst possible outcome when alive (best to worst), and ensures that patients who die are included in all analyses. The EQ-5D Health Utility State (HUS) gives death a score of 0.

- Modified Rankin Scale (mRS), 0 to 5 with death = 6
- Barthel Index (BI), 100 to 0 with death = -5
- Scandinavian Stroke Scale (SSS), 58 to 0 with death = -1
- EQ-5D HUS, 1 to -0.594 with death = 0
- EQ-VAS (visual analogue scale), 100 to 0 with death = -1
- Zung Depression Scale (ZDS), 25 to 100 with death = 102.5
- Telephone Interview for Cognitive Status (TICS), 39 to 0 with death = -1
- Verbal fluency (animal naming), ∞ to 0, with death = -1
- Telephone Mini Mental Status Exam (t-MMSE), 18 to 0, with death = -1

Patients who are still in hospital at day 90 will have a length of stay assigned at 110 days. Similarly, death will be censored at day 110.

4.3.3 Statistical assumptions

4.3.3.1 Proportionality of odds

The treatment effects on ordered categorical data will be compared using ordinal logistic regression (OLR) with adjustment for the prognostic covariates as listed in 3.3.2, plus use of alteplase. OLR assumes proportionality of odds and this will be tested using a

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

likelihood ratio test. If the proportional odds assumption is not met, OLR will still be used and the lack of proportionality of odds highlighted. In this circumstance, the odds ratio may remain relevant (and probability value accurate) providing the treatment effect is relatively consistent across the spread of mRS scores.

4.3.3.2 Alpha spending

The Data Monitoring Committee performs safety assessments using the '3 standard deviation' approach; hence, no significant spending of alpha has occurred during the trial. All analyses will be two-tailed and a p-value of <0.05 will denote statistical significance; 95% confidence intervals will be provided. Adjustment for multiple comparisons will not be performed but all contrasts will be declared.

The primary and secondary outcomes follow here. Although not all the secondary outcomes will be presented in the two primary papers (GTN vs no GTN, continue vs stop pre-stroke antihypertensive medication), they will be used in secondary papers and are given here for completeness.

4.3.3.3 mRS levels

Although some previous studies (e.g. SAINT-I/II, ECASS-3²⁹⁻³¹) combined death with severe disability (i.e. mRS categories 5 and 6 were combined), these mRS categories will be analysed separately in ENOS since blood pressure treatment may influence both mortality and disability.

4.4 Primary outcome

4.4.1 Primary outcome measure

The seven-level ordered categorical modified Rankin Scale (mRS):^{22,32}

- 0 No symptoms at all.
- 1 No significant disability, despite symptoms; able to carry out all usual duties and activities.
- 2 Slight disability; unable to carry out all previous activities but able to look after own affairs without assistance.
- 3 Moderate disability; requiring some help, but able to walk without assistance.
- 4 Moderately severe disability; unable to walk without assistance and unable to attend to own bodily needs without assistance.
- 5 Severe disability; bedridden, incontinent and requiring constant nursing care and attention.
- 6 Dead.

4.4.2 Primary outcome analysis

All 7 levels of the mRS will be used with analysis by OLR with adjustment for baseline covariates:²⁴⁻²⁶

- Age; sex (female, male); pre-morbid mRS; history of previous stroke (no, yes); diabetes mellitus (no, yes); current use of nitrate therapy (no, yes); stroke severity (Scandinavian Stroke Scale, SSS); total anterior circulation syndrome (no, yes); stroke pathological type (non, IS, ICH); systolic BP (SBP); treated with rt-PA (yes, no); feeding status (oral, non oral); time onset to randomisation.
- The comparison of GTN vs no GTN will also include the covariate for Continue vs stop pre-stroke antihypertensive medication.
- The comparison of Continue vs stop pre-stroke antihypertensive medication will also include the covariate for GTN vs no GTN.

Covariate adjustment with ordered categorical (mRS) or continuous (age, SSS, SBP, time) variables will use the original, not dichotomised, data.

4.4.3 Primary outcome subgroup analyses

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

The effect of the two interventions (GTN versus no GTN; continue versus temporarily stop pre-stroke antihypertensive medication) on the primary outcome will be performed within the following pre-specified subgroups of participants. Subgroup analyses will be performed on mRS using ordinal logistic regression. An interaction test between each subgroup and treatment will be performed.

4.4.3.1 Primary publications

- a) Age - ≤ 70 , > 70 years
- b) Sex - female, male
- c) History of prior stroke - no, yes
- d) Stroke severity (/58) - SSS > 40 , 30-40, < 30
- e) Oxfordshire Community Stroke Project Classification²³ - LACS, POCS, PACS TACS
- f) Stroke pathological type - ischaemic stroke, unknown, ICH
- g) Mean blood pressure (mmHg) - SBP ≤ 160 , 161-180, 181-200, > 200
- h) Atrial fibrillation/flutter - absent, present
- i) Non-oral feeding (surrogate for dysphagia) - absent, present
- j) Carotid stenosis (ipsilateral %) - 0-49, 50-69, 70-99, 100 (as determined locally)
- k) Time to randomisation (hours) - ≤ 6.0 , 6.1-12.0, 12.1-24.0, 24.1-36, > 36
- l) Treatment with alteplase - present, absent

Additionally, for GTN versus no GTN

- a) History of recent nitrate exposure - no, yes
- b) Pre-stroke antihypertensive medication randomisation - not relevant, continue, stop

Additionally, for continue versus stop pre-stroke antihypertensive medication:

- a) Pre-stroke antihypertensive class - angiotensin-converting enzyme inhibitor, angiotensin-II receptor antagonist, renin inhibitor, β -blocker, calcium-channel blocker, diuretic, α -blocker, centrally acting agent, other (participants may appear in more than one subgroup)
- b) Number of classes of antihypertensive drugs pre-stroke - 1, 2, 3, 4, 5, > 5
- c) GTN randomisation - GTN, no GTN

4.4.3.2 Secondary publications

In secondary papers, the effect of treatment on mRS will also be assessed in additional sub-groups:

- a) Geographical region (section B.2.1)
- b) TOAST criteria (small vessel, large vessel, cardioembolism, dual pathology, other)
- c) Carotid stenosis ($\geq 50\%$) - none, contralateral, ipsilateral, bilateral
- d) Old lesion on baseline neuroimaging - no, yes
- e) Lesion size - 1, 2, 3, 4 (Appendix B, section 2.9.2)
- f) Mass effect - 0,1 vs 2-4 vs 5,6 (Appendix B, section 2.9.3)

4.4.4 Sensitivity analyses

Several sensitivity analyses will be performed as a reference for the primary analysis. The method of analysis is given: BLR: binary logistic regression; OLR: ordinal logistic regression

- | | |
|--|----------------------------|
| a) mRS, unadjusted | OLR |
| b) mRS, with additional adjustment for Geographical region | OLR |
| c) Dead or dependent (mRS 3-6, adjusted) | BLR |
| d) Dead or dependent (mRS 3-6, unadjusted) | BLR |
| e) Global outcome, mRS > 1 and BI < 95 , adjusted | Wald test ^{33,34} |

Comparison (d) is the original trial primary outcome prior to switching to an ordinal analysis.

4.5 Secondary outcomes

Secondary outcomes are listed by their timing. Analysis methods will include: MLR: multiple linear regression; analyses will be adjusted as in section 4.4.2 and also performed unadjusted for completeness.

4.5.1 Events by day 7 (end of treatment)

a) Death	BLR
b) Symptomatic intracranial haemorrhage	BLR
c) Major extracranial haemorrhage	BLR
d) Symptomatic recurrent stroke	BLR
e) Impairment (SSS)	MLR
f) Impairment (calculated NIHSS ³⁵)	MLR
g) Clinical neurological deterioration	BLR
h) Neurological deterioration ²²	BLR
i) Headache that required treatment	BLR
j) Symptomatic hypotension that required treatment	BLR
k) Symptomatic hypertension that required treatment	BLR
l) Symptomatic venous thromboembolism	BLR

4.5.2 Hospital events (collected at discharge or on death)

a) Length of stay in hospital	MLR
b) Discharge disposition (death/institution/home)	OLR

4.5.3 Outcome at 90 days (end of follow-up)

This are determined centrally by a telephone call between the patient (or carer) and an assessor blinded to treatment and earlier clinical information:

a) Death (censored by day 110)	BLR
b) Time to death (censored at 110 days) Meier curve)	Cox regression (Kaplan Meier curve)
c) Barthel Index (BI)	MLR
d) Dead or disabled (BI <60)	BLR
e) Quality of life (HUS derived from EQ-5D)	MLR
f) Quality of life (EQ-5D VAS)	MLR
g) t-MMSE	MLR
h) TICS-M	MLR
i) Verbal fluency	MLR
j) Zung Depression Scale (ZDS, mood)	MLR

4.6 Safety analyses – Serious Adverse Events

Safety analyses are listed together with their preferred method of analysis. All SAEs reported by the investigator are adjudicated by a member of the independent adjudicator panel who is blinded to treatment. The adjudicated SAE categorisation will be presented for all analyses. The number of participants with a SAE rather than the number of SAE will be analysed. Comparisons will be performed on all patients.

4.6.1 SAEs by day 10 (7 days of treatment + 3 days of washout)

a) Serious adverse event, number of patients	BLR
--	-----

4.6.2 SAEs by day 90 (end of follow-up)

a) Serious adverse event, number of patients	BLR
--	-----

Serious adverse events by 90 days will be tabulated as the number of participants with an event in each treatment group, and the number of events in each treatment group,

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

by the following subgroups. BLR will be used to identify any differences between treatment groups.

- a) System organ class
- b) Event category within system organ class
- c) Time of onset relative to treatment (before, during, after)
- d) Median time to event by event category
- e) Severity (mild, moderate, severe)
- f) Relationship to study drug (definitely not, unlikely, possibly, probably, definitely)
- g) Fatal, non-fatal
- h) Fatal by event category

Common serious adverse events that will be reported are listed in Appendix C table 4.

4.7 Compliance

Compliance with allocated treatment will be tabulated. Patients receiving at least the first 4 doses of treatment are considered to have received full treatment. The following data will be presented separately for GTN vs. no GTN, and continue vs. temporarily stop pre-stroke antihypertensive medications

- a) Number (%) of participants who received all 7 days of allocated treatment
- b) Number (%) of participants who received at least the first 4 days of allocated treatment
- c) Number (%) of participants who received at least the first allocated treatment
- d) Number (%) of participants who did not receive any of the allocated treatment

In those participants who did not receive all the first 4 days of allocated treatment, the reason for non-compliance will be given:

- a) Discharged before day 4
- b) Physician withdrew participant
- c) Adverse event, unacceptable
 - a. Headache
- d) Serious adverse event
- e) Consent withdrawn by participant or relative
- f) Death
- g) Other reason

Reasons for non-compliance	All	GTN	No GTN
Reasons for non-compliance	All	Continue	Stop
Participants randomised			
Compliance			
Received all 7 days of treatment			
Received first 4 days of treatment			
Received first treatment			
Did not receive any randomised treatment			
Non-compliance by day 4 (%)			
Discharged			
Physician withdrew participant			
Adverse event, unacceptable			
Headache			
Serious adverse event			
Consent withdrawal by participant or relative			
Death			
Other			

Note: Patients discharged before day 7 were given their remaining part of their course of GTN to complete at home.

4.8 Analysis methods

Data variables will, in the main, be analysed using binary logistic regression (BLR), Cox logistic regression (CLR); ordinal logistic regression (OLR) or multiple logistic regression (MLR), thereby allowing adjustment for baseline measures and other covariates (as listed partially in section 4.4.3).

4.8.1 Clinical variables

- BLR: Death; Death or deterioration (day 7); Recurrence (day 7); Symptomatic intracranial bleed (sICH); Discharged to or at Home
- CLR: Death
- OLR: Modified Rankin Scale (mRS) [/6];
- MLR: Scandinavian Stroke Scale (SSS, /58); Length of stay in hospital; Barthel Index (BI, /100); telephone Mini-Mental State Examination (tMMSE); Telephone Interview of Cognition Scale (TICS, /39); Animal naming (/∞); Zung Depression Scale (ZDS, /100); Health Utility State (HUS, /1); EuroQoL Visual Analogue Scale (EQ-VAS, /100)

4.8.2 Imaging variables

- BLR: Loss of grey-white definition; Loss of basal ganglia outline; Hypodensity; Mass effect; ICH mean radial expansion > 1mm; Second lesion; Hyperdense artery
- OLR: Lesion site; Lesion size: MCA, lacunar, cerebellum or brainstem; Mass effect, degree [/6]; Haemorrhagic Transformation of Infarct; Hypoattenuation; Mass effect score (greatest of Uncal> shift> ventricular> sulcal); Middle Cerebral Artery 1/3 (if MCA, >1/3, <1/3, no lesion); ASPECTS score; ICH diameter, max – adjudicated; ICH shape [/5]; ICH density [/5]; IVH Graeb [/12];³⁶ IVH modified Graeb [/32];³⁷
- MLR: Volume (ABC/2), absolute (ml); Volume (ABC/2), relative (%); Diameter, max (cm); Haematoma shape index; Haematoma mean density; Haematoma density index; IVH volume

4.8.3 Procedures

The two primary papers will be analysed using two separate sets of statistical programmes, one written specifically for the purpose and the other based on the Data Monitoring Committee report. A further analysis of a sub-set of the main results will be performed using a third statistical programme. This will allow the results to be cross-checked.

To maximise recruitment, maximise time for analysis and interpretation of the results, and allow presentation of the final results at the European Stroke Conference in early May 2014, a soft-lock and preliminary analysis will be performed once the last patient has had their final outcome recorded in early January 2014. Following final data cleaning on the last patients to be recruited, a hard-lock will be performed in late January/early February and the results of this considered by the Trial Steering Committee in mid February 2014. The preliminary interpretation will be performed after soft-lock by PMB, NS, JW and SP; they will not be involved in resolving any final queries to maintain the integrity and blinding of the final database. The approach of soft-lock then hard-lock is a standard approach in large trials and does allow more time to be spent on considering the results of a trial, their interpretation and presentation for publication.

1 DEFINITIONS OF EVENTS/OUTCOMES

1.1 Deep vein thrombosis (DVT), symptomatic, by/at day 7

The clinical suspicion of DVT will need confirmation by either venography or ultrasound examination.

1.2 Disposition

Disposition at 90 days and discharge disposition is categorised as death, institution or home.

- Institution refers to warden controlled, residential home, care home, nursing home, still an inpatient, or readmitted to hospital.
- Home refers to home alone, home with spouse/carer and carer's home.

1.3 Extracranial haemorrhage, major

Clinically overt bleeding associated with one or more of:

- Transfusion of > 2 red cell units of blood
- A fall in haemoglobin of 20 g/l (=2 g/dl, = 1.24 mmol/l)
- Bleeding into retroperitoneum, intraocular space or major joint
- Bleeding leading to permanent cessation of trial interventions

1.4 Feeding status

Feeding status will be defined as:

- Oral: normal diet, soft diet
- Non-oral: nasogastric tube fed, PEG-tube fed, iv/sc fluids, no feeding/fluids

1.5 Headache, requiring treatment by day 7

A headache occurring during GTN/no GTN treatment that necessitates intervention, including withdrawing GTN/no GTN treatment.

1.6 Hypertension, symptomatic by day 7

A rise in blood pressure necessitating intervention to reduce it.

1.7 Hypotension, symptomatic by day 7

A symptomatic fall in blood pressure of > 20% as compared with baseline necessitating intervention with intravenous colloid or crystalloid (saline).

1.8 Neurological deterioration, by day 7

A reduction in SSS of >4 points, or decrease in consciousness level by >2 points, as compared with baseline.²²

1.9 Neurological deterioration, clinical by day 7

Neurological deterioration determined clinically.

1.10 Pulmonary embolism (PE), symptomatic by day 7

The clinical suspicion of PE will need confirmation by either high-probability ventilation-perfusion lung scintigraphy, pulmonary angiography, inconclusive V/Q scan and DVT, or lead to death.

1.11 Recurrent stroke, symptomatic, by/at day 7

Classified as haemorrhagic or ischaemic (if documented by CT/MR scan or autopsy), or of unknown type. The time from stroke onset and side will be noted. (This definition deliberately does not attempt to differentiate true recurrence from extension of the presenting lesion since this is clinically and radiologically difficult unless recurrence

occurs in a new arterial territory.)

1.12 Intracranial haemorrhage, symptomatic by day 7

Neurological deterioration or death, associated with intracranial haemorrhage found on CT/MR scan or autopsy.

1.13 Time at home

Calculated as time from date of discharge to day 90 or death if earlier; those who die in hospital or are discharged to a non-home setting are given a score of zero. Readmission to hospital is not counted in this time.

1.14 Venous thromboembolism, symptomatic by day 7

Symptomatic DVT and/or symptomatic pulmonary embolism

2 OTHER DEFINITIONS AND NOTES

2.1 Geographic region

This is categorised into Africa, America north, Asia east, Asia south, Asia south-east, Australasia, British Isles, and Europe. Each geographical region is defined as the following countries, each of which have randomised at least one participant into the ENOS trial:

- a) Africa: Egypt
- b) America, north: Canada
- c) Asia, east: China, Hong Kong
- d) Asia, south: India, Sri Lanka
- e) Asia, south-east: Malaysia, Philippines, Singapore
- f) Australasia: Australia, New Zealand
- g) British Isles: Eire, UK
- h) Europe: Denmark, Georgia, Greece, Italy, Norway, Poland, Romania, Spain, Sweden

2.2 Haemodynamic variables, calculated

These are calculated from SBP, diastolic blood pressure (DBP) and HR measurements at baseline (day 0) and on days 1-6. Mean, peak, and standard deviation (SD), of SBP/DBP/HR are calculated from available measurements at that time point.

Coefficient of Variation, $CV=SD/mean$.

- a) SBP, mean
- b) SBP, peak
- c) SBP, intra-visit variability = SD of SBP separately at each time point
- d) SBP, CV
- e) DBP, mean
- f) DBP, peak
- g) DBP, intra-visit variability = SD of DBP separately at each time point
- h) DBP, CV
- i) HR, mean
- j) HR, peak
- k) HR, intra-visit variability = SD of HR separately at each time point
- l) HR, CV
- m) Mean arterial pressure (MAP) = $\text{mean DBP} + (\text{mean SBP} / 3)$
- n) Mean pressure (MP) = $(\text{mean DBP} + \text{mean SBP}) / 2$
- o) Pulse pressure (PP) = $\text{mean SBP} - \text{mean DBP}$
- p) Pulse pressure index (PPI) = PP / MAP

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

- q) Rate-pressure product (RPP) = mean SBP x mean HR
- r) Mean SBP across days 1-4
- s) Inter-visit Variability (SBP-inter SD) = SD of SBP across days 1-4
- t) CV SBP across days 1-4
- u) SBP peak across days 1-4

2.3 Acute Stroke Unit (ASU)

A high-dependency nursing unit (or area) caring only/mainly for patients with acute stroke and providing close monitoring of neurological and vascular signs.

2.4 Stroke Rehabilitation Unit (SRU)

A dedicated rehabilitation unit (or area) caring only/mainly for patients with recent stroke and providing multi-disciplinary therapy (e.g. physiotherapy, occupational therapy, speech & language therapy).

2.5 Final diagnosis: ischaemic stroke, ICH, unknown type of stroke, non-stroke

The final diagnosis for the qualifying event will be determined using information from the recruiting site based on the clinical presentation, history of recovery and interpretation of the brain scan. The resulting diagnosis will be compared with that from central adjudication of the baseline brain scan. If there is a discrepancy between site and adjudication, the site will be contacted to clarify the diagnosis and the scan reviewed centrally by JMW; ultimately the site's final diagnosis will be used if agreement cannot be obtained.

Final diagnosis will comprise one of the following: ischaemic stroke (which includes a normal CT brain scan), ICH, stroke of unknown pathological type, or non-stroke (e.g. tumour, abscess, subdural bleed).

Final diagnosis will be determined using the following source(s):

1. Hospital event form (completed at discharge or death: final diagnosis question). If this is unavailable use 2.
2. Day 7 form (baseline CT/MRI scan result question). If this is unavailable use 3.
3. Baseline form – as used for randomisation (baseline CT/MRI scan result question). If this is unavailable use 4.
4. If the diagnosis of stroke is not known according to the data sources above (e.g. due to early death and no autopsy), then the diagnosis will be assigned as 'Stroke, type unknown'.

2.6 Date of death

Dates of death have multiple sources and these are ranked for determining the date (in case a particular source is missing the information):

1. MRIS/ONS feedback, if UK patient
2. Serious adverse event form
3. Hospital event form
4. Day 7 form

If there is a discrepancy in the recorded date then the site are approached to confirm the correct date.

2.7 EQ-5D and Health Utility States (HUS)

EQ-5D is a measure of health status and is composed of the EQ-5D descriptive system and EQ visual analogue scale (EQ VAS). The EQ VAS is a self-rated scale from 0 (worst imaginable health state) to 100 (best imaginable health state). The EQ-5D descriptive system has 5 dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Each dimension has 3 levels; no problems (level 1), some problems (level 2), severe problems (level 3).³⁸

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

There are 243 possible health states. Each health state is referred to by a 5 digit code, e.g., 11111. The EQ-5D health states can be converted into a single summary index ranging from 1.00, i.e. full health (11111), to -0.594 (33333, worst possible state using the UK version of the time trade-off algorithm), with death assigned to 0.³⁸ The conversion is made by applying the formula in Table 5, which deducts weights applied to each dimension from the starting value of 1. The UK version of the EQ-5D index algorithm using the time trade off value set will be used for all patients.¹⁹

EQ-5D index scoring algorithm (Time trade-off: UK version)

	Weight
Full health (11111)	1
At least one 2 or 3	-0.081
At least one 3	-0.269
Mobility	
Score 2	-0.069
Score 3	-0.314
Self-care	
Score 2	-0.104
Score 3	-0.214
Usual activities	
Score 2	-0.036
Score 3	-0.094
Pain/discomfort	
Score 2	-0.123
Score 3	-0.386
Anxiety/depression	
Score 2	-0.071
Score 3	-0.236

For example, a health state of 32211 will convert to 0.196 ($=1-0.81-0.269-0.314-0.104-0.071$).

2.8 Protocol violations

For per protocol analyses, patients who have one or more of the following protocol violations will be excluded from the per protocol population:

2.8.1 All analyses

- Failure to obtain consent or assent
- Antihypertensive medication received post-stroke and pre-randomisation
- Age < 18 years
- Randomised > 48 hours
- No limb weakness at any point in presentation
- Glasgow Coma Scale (GCS) < 8 at baseline
- Systolic BP < 140 mmHg or > 220 mmHg at baseline
- Final diagnosis non-stroke
- Final diagnosis unknown because no neuroimaging or autopsy

2.8.2 GTN vs no GTN

- Failure to stop pre-stroke nitrates
- No GTN received for first 4 days if randomised to GTN
- GTN received in first 4 days if randomised to no GTN

2.8.3 Continue vs stop pre-stroke antihypertensive medication

- Failure to identify pre-stroke antihypertensive medication

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

- Antihypertensives received during first 4 days if randomised to stop
- Antihypertensives not received during first 4 days if randomised to continue

2.9 CT/MR image adjudication

All patients should have a diagnostic CT or MRI scan, ideally before randomisation or at least within one week of randomisation. A second CT or MRI scan is performed at the end of treatment (7 ± 2 days, or earlier if clinically warranted) to allow the effect of treatment on stroke lesion development to be assessed; principal investigators can opt in or out of the second scan. Both baseline and second CT/MRI scans are assessed by an independent adjudicator blinded to treatment assignment. Lesion size is assessed by an independent assessor, i.e. not by the investigator.

2.9.1 Infarct visibility (as per IST-3 scheme ©JMW 2012³⁹)

Infarct size is coded (small=1 through to large=4) using adjudicated data for both baseline and, where done, day 7 CT/MR scans.

2.9.2 Site

M† =MCA = any lesion in the MCA territory
AS =Infarct of up to half of ACA territory
AL =Infarct of more than half of ACA territory
PS =Infarct of up to half of PCA territory
PL =Infarct of more than half of PCA territory
MAS=M+AS†
MAL=M+AL†
MPS=M+PS†
MPL=M+PL†
MAP=Infarct of whole MCA, ACA and PCA territories4
L† =Lacunar
B† =Borderzone
C† =Cerebellum
S† =Brainstem
CS†=Cerebellum and brainstem

† code sub-territory sites as in 2.13.10.2

2.9.3 Sub-territory sites

MCA sub-territory codes

1=small cortical infarct 1
2=basal ganglia infarct (>2x2x2cm) 2
3=infarct of white matter lateral to lateral ventricle (>2x2x2cm) 2
4=infarct of anterior half of peripheral MCA territory 2
5=infarct of posterior half of peripheral MCA territory 3
6=infarct of whole of peripheral MCA territory 3
7=6+infarct of lateral part of basal ganglia 4
8=infarct of whole of MCA territory 4

Lacunar/Borderzone sub-territory codes

9=lacune in internal capsule/lentiform all 1
10=lacune in internal border zone
11=lacune in centrum semiovale
12=lacune in thalamus
13=lacune in brainstem, including pons (not shown)
14=anterior (mainly) border zone
15=posterior (mainly) border zone

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

Cerebellum sub-territory codes	
16=small cortical (not shown)	1
17=<1/2 hemisphere (medium) (not shown)	2
18=>1/2 hemisphere (not shown)	3

Brainstem sub-territory codes	
19=small, i.e. <1/2 medulla (not shown)	1
20=extensive, i.e. pons + medulla (not shown)	2

Degree of mass effect codes	
0=no swelling	
1=effacement of sulci overlying stroke	
2=1+minor effacement of adjacent lateral ventricle	
3=1+complete effacement of adjacent lateral ventricle	
4=1+effacement of lateral and third ventricle	
5=4+shift of the midline away from side of ventricle	
6=5+effacement of basal cisterns	

2.9.4 Infarcts

Loss of grey/white matter cortex definition	yes/no
Loss of basal ganglia outline	yes/no
Hypodensity present	yes/no
Mass effect	yes/no, if yes each yes/no
• Succal effacement	
• Ventricular effacement	
• Midline shift	
• Uncal herniation	
1/3 MCA territory	yes/no
ASPECT score, for each region	yes/no
Second discrete lesion	yes/no
Hyperdense artery	yes/no, if yes then site

2.9.5 Haemorrhage

By presence, importance and size (<3, 3-5, 5-8, >8 cm):

- Petechial
- Haemorrhagic transformation of infarct
- Parenchymal haematoma (no infarct)
- Parenchymal haematoma (remote from infarct)
- Subdural haematoma
- Subarachnoid haemorrhage
- Extradural haemorrhage

2.9.6 Other features

Reduction in brain tissue volume: none, moderate severe:

CONFIDENTIAL: ENOS SAP APPENDIX 20130811

- Central
- Cortical

Periventricular lucencies: none, restricted to region adjoining ventricles, from ventricle to cortex

- Anterior white matter
- Posterior white matter

Old vascular lesions: each yes/no

- Cortical infarct(s)
- Striatocapsular infarct(s)
- Borderzone infarct(s)
- Lacunar infarct(s)
- Brainstem/cerebellar infarct(s)

Non-stroke lesions, each yes/no

- Cerebral tumour
- Encephalitis
- Cerebral abscess
- Other, e.g. contusion

APPENDIX C. TABLES AND FIGURES IN PRIMARY PUBLICATIONS

Authors

ENOS Trial Investigators

Format

The primary publications for the GTN vs no GTN, and continue vs stop pre-stroke antihypertensive medications will share the same format for tables and figures as highlighted below. Any additions to, or differences in, one or other publication are given separately.

1 Table 1. Baseline characteristics

1.1 Both GTN/no GTN and Continue/Stop publications

Table 1. Baseline characteristics of patients enrolled into the ENOS trial. Data are number (%), median [interquartile range] or mean (standard deviation).

	All patients	GTN	No GTN

APPENDIX E. PLANNED PUBLICATION: BASELINE DATA

Authorship

To be decided.

Title

Characterisation of patients enrolled into the 'Efficacy of Nitric Oxide' in Stroke (ENOS) trial.

Authors

Members of Trial Steering Committee, International Advisory Committee and Trial Management Committee.

Aim

To characterise the patients enrolled into ENOS. For submission after enrolment of the last patient in quarter 4 2013.

Patients

All randomised patients.

Table 3. Issues with the trial.

Issue	Explanation	Effect/Response
Sponsorship	Insurance and contracting issues prevented a number of countries from participating in ENOS.	Reduced world coverage and recruitment.
Recruitment, rate low	Recruitment limited by: Severe acute respiratory syndrome (SARS), Bird flu, competing trials, trial fatigue.	Delayed recruitment at various sites, especially in Singapore.
Recruitment, rate too high	Two sites over-recruited: Site A: Outcome was poorly recorded, and had several losses to follow-up. A limited number of scans were available. Site B: Review of baseline and follow-up data, consent forms, treatment charts and brain scans revealed no problem.	A: Site closed. B: No action.
Recruitment, delayed	Tendency for patients to be recruited during day 2, in spite of repeated requests to investigators to focus on recruiting patients at the time of presentation to hospital.	Extended mean time to recruitment.
Randomisation to continue/stop	Patients not on pre-stroke antihypertensive drugs randomised in error (N=).	Sites training on inclusion criteria
Non-randomisation to continue/stop	Patients on pre-stroke antihypertensive drugs not randomised because drug(s) not recognised as an antihypertensive (N=).	Sites given full international list of anti-hypertensive agents.
Non-availability of placebo GTN patches	Placebo patches were made available by one manufacturer for the first pilot trial. ¹⁰ Pilot trials 2-4 used a single-blind design with GTN patch (or similar area of skin) covered by a gauze dressing. ¹¹⁻¹³	ENOS designed as single-blind study as for pilot trials 2-4.
Loss of availability of GTN patches	In China, GTN patches were sourced from a local manufacturer. A reduction in the national reimbursement for manufacturing these patches meant that the company ceased their production. Importation of patches from overseas proved too complicated to organise.	Cessation of recruitment in China.
Inappropriate GTN treatment	GTN given open-label to all patients at one site irrespective of randomisation.	Data from this site excluded from all analyses (exclusion in 2012, i.e. prior to data lock).
Theft of data	Theft of paper case report forms and brain scan films from one site relating to patients.	Missing follow-up and CT scan data.
Withdrawals	Withdrawal from follow-up (N=) or lost to follow-up (N=).	Missing primary outcome data.

Table 4. Univariate correlations between baseline characteristics for: age, sex, stroke severity (Scandinavian Stroke Scale, SSS), stroke pathological type (ischaemic, haemorrhage), systolic blood pressure (SBP), time to randomisation, and year of randomisation. Correlations by point biserial or Spearman’s tests; data are regression coefficient and p value.

	Age	Sex, male	Severity (SSS)	Stroke type, bleed	Systolic BP	Time to randomisation	Year of randomisation

APPENDIX F. PLANNED PUBLICATION: GLYCERYL TRINITRATE AND/OR CONTINUING PRE-STROKE ANTIHYPERTENSIVE MEDICATIONS IN ACUTE ISCHAEMIC STROKE

Authorship

Kailash Krishnan, ..., Rob Dineen, Joanna Wardlaw, Philip Bath

Title

Glyceryl trinitrate and/or continuing pre-stroke antihypertensive medications in acute ischaemic stroke.

Authors

To include neuroimaging adjudicators.

Aim

To assess the effect of GTN vs no GTN, and continue vs stop temporarily pre-stroke antihypertensive medications, in patients with a final diagnosis of acute ischaemic stroke.

Patients

All randomised patients with acute ischaemic stroke, by intention-to-treat.

Layout

The publication will follow the format of the two primary publications (baseline characteristics, BP profile, clinical outcomes, SAEs, mRS distribution, survival) but will report the effect of both intervention comparisons (GTN vs no GTN, continue vs stop pre-stroke antihypertensive agents) in patients with acute ischaemic stroke as the final diagnosis. In addition, adjudicated information on baseline imaging data will be described (reporting the imaging variables in the table below), as will the effect of the interventions on day 7 imaging parameters (adjusted for baseline) where available (table).

Imaging data

The effect of the interventions on imaging parameters will be assessed where both baseline and day 7 data are present. The method of analysis is given for each imaging parameter.

Table 1. Baseline IS characteristics

Baseline demographic, clinical and neuroimaging characteristics of patients with acute ischaemic stroke. Data are number (%), median [interquartile range] or mean (standard deviation).

APPENDIX H. PLANNED PUBLICATION: HAEMODYNAMIC EFFECTS OF GTN VERSUS NO GTN, AND CONTINUE VERSUS STOP PRE-STROKE ANTIHYPERTENSIVE MEDICATIONS

Authorship

..., Philip Bath

Title

Effect of glyceryl trinitrate and/or continuing pre-stroke antihypertensive medications on blood pressure and other haemodynamic parameters, and relationship between changes and functional outcome.

Aim

To assess the effect of GTN vs no GTN, and continue vs stop temporarily pre-stroke antihypertensive medications, on blood pressure, heart rate and their derivatives in patients with acute stroke.

Patients

All randomised patients with acute stroke, by intention-to-treat. Haemodynamic measures will be calculated as in appendix B, section 2.2.

Table 1. Baseline haemodynamic parameters

APPENDIX I. PLANNED PUBLICATION: GTN, HEADACHE AND OUTCOME

Authorship

Kailash Krishnan, ..., Philip Bath

Title

Relationship of GTN-related headache with outcome (as in PRoFESS – submitted)

Background

The PRoFESS mega-trial found that the headache that occurs with dipyridamole - a nitric oxide modifying drug – is associated with less recurrence after ischaemic stroke [publication submitted]. Since the headache that occurs with GTN is mediated by a similar mechanism, GTN-associated headaches may also be associated with subsequent outcome.

Hypotheses

- The presence of a headache by day 7 in patients taking GTN is associated with a better functional outcome and less recurrence than those with out a headache.
- The presence of a headache by day 7 in patients taking control is not associated with outcome.

Patients

All ENOS patients who received at least their first treatment (GTN/no GTN), who have information on headache (yes/no) at day 7, and who have functional outcome (mRS) recorded at day 90. SAEs for headache within the first 7 days will be validated against data for headache on the day 7 form.

Table 1. Baseline table

APPENDIX J. PLANNED PUBLICATION: EFFECT OF GTN ON FEEDING STATUS

Authorship

..., Shaheen Hamdy, David Smithard, David Cohen, ... Niki Sprigg, Philip Bath

Title

Effect of transdermal glyceryl trinitrate on feeding status at day 7 after stroke, and relationship of feeding status with functional outcome: results from the 'Efficacy of Nitric Oxide in Stroke' (ENOS) trial.

Hypothesis

GTN relaxes smooth muscle and therefore may improve the oesophageal phase of swallowing. A small/pilot randomised trial of nifedipine, a calcium channel blocker that also relaxes oesophageal smooth muscle, reported potentially beneficial effects.⁵⁵

Patients

Patients in ENOS with information on feeding status at both baseline and day 7, and a final diagnosis of strokes. Analysis by intention-to-treat.

Feeding status is defined on a 6-level ordered categorical scale (normal diet, soft diet, nasogastric tube fed, PEG-tube fed, iv/sc fluids, no feeding/fluids).

Since dysphagia was not directly assessed, dysphagia is defined clinically as patients who cannot take fluids/food orally, i.e.:

- Not dysphagic/oral feeding: normal diet, soft diet
- Dysphagic/no oral feeding: NGT-feeding, PEG/RIG-feeding, iv/sc fluids or no feeding/fluids
- Missing data - No information on feeding status

Table 1. Baseline data

Characteristics of patients with and without clinical dysphagia at baseline. Data are number (%) or mean (standard deviation). Comparison of patients who have versus do not have oral feeding by Chi-square test or t test.

Survival curve for dysphagia vs no dysphagia for (a) all patients to 100 days, and (b) UK patients to 4000 days. Comparisons by Cox regression adjusted for age, sex, stroke severity (SSS), TACS, stroke pathological type (ICH, ischaemic), SBP, time between stroke and randomisation, baseline feeding status and treatment assignment.

APPENDIX K. PLANNED PUBLICATION: SPONTANEOUS INTRACEREBRAL HAEMORRHAGE BETWEEN DIFFERENT WORLD REGIONS

Authorship

Kailash Krishnan, ..., Niki Sprigg, Joanna Wardlaw, Philip Bath

Title

Comparison of acute spontaneous intracerebral haemorrhage between different world regions: patients, haematoma and outcomes in the ENOS trial.

Authors

To include neuroimaging adjudicators and K Krishnan.

Aim

To compare patients and haematoma characteristics, and outcomes, between different regions of the world. Approaches used in previous publications comparing stroke outcomes between countries ^{46,48,56} will be followed.

Patients

All randomised patients with acute spontaneous intracerebral haemorrhage, by intention-to-treat:

- a) Africa: Egypt
- b) America, north: Canada
- c) Asia, east: China, Hong Kong
- d) Asia, south: India, Sri Lanka
- e) Asia, south-east: Malaysia, Philippines, Singapore
- f) Australasia: Australia, New Zealand
- g) British Isles: Eire, UK
- h) Europe: Denmark, Georgia, Greece, Italy, Norway, Poland, Romania, Spain, Sweden

APPENDIX L. PLANNED PUBLICATION: COMPARISON OF PATIENTS WHO TOOK VERSUS DID NOT TAKE PRE-STROKE ANTIHYPERTENSIVE MEDICATIONS: BASELINE CHARACTERISTICS AND OUTCOMES

Authorship

...

Title

Comparison of patients who took versus did not take pre-stroke antihypertensive medications: baseline characteristics and outcomes.

Hypothesis

Patients taking pre-stroke antihypertensive medications will have more vascular risk factors and a worse outcome than those not on such medications.

Patients

Patients with confirmed stroke, by intention to treat.

Table 1. Baseline characteristics of included trials

Description of the trials and their participants. Trials are ordered by mean time to recruitment. Data are number (%) or mean (standard deviation).

Table based on baseline data publication.

APPENDIX M. PLANNED PUBLICATION: TEMPORAL EFFECTS OF GTN ON FUNCTIONAL OUTCOME

Authorship

..., Sandeep Ankolekar, Tim England, Kailash Krishnan, Parveen Rashid, Gill Sare, Niki Sprigg, Mark Willmot, Philip Bath

Title

Effect of transdermal glyceryl trinitrate on functional outcome in acute stroke by time to treatment: an individual patient data meta-analysis of all ultra-acute, acute, and subacute randomised trials of GTN.

Hypothesis

The effect of GTN on functional outcome may vary by time to treatment, as with alteplase.⁵⁷

Patients

All patients in GTN-1/2/3, RIGHT, ENOS and any other identified randomised controlled trials of GTN,¹⁰⁻¹³ by intention to treat. The publication will follow the approaches published for alteplase.^{57,58}

APPENDIX N. PLANNED PUBLICATION: CONTINUING VERSUS STOPPING PRE-STROKE ANTIHYPERTENSIVE MEDICATIONS IN ACUTE STROKE: A META-ANALYSIS OF INDIVIDUAL PATIENT DATA FROM RANDOMISED CONTROLLED TRIALS

Authorship

Tom Robinson, ..., Ken Lees, Philip Bath

Title

Comparison of continuing or temporary stopping of pre-stroke antihypertensive medication in acute stroke: a prospective meta-analysis of individual patient data from randomised controlled trials.

Hypothesis

Continuing pre-stroke antihypertensive therapy lowers BP and reduces poor functional outcome as opposed to temporary stopping of such treatment.

Patients

Patients recruited into trials comparing continuing versus stopping pre-stroke antihypertensive agents in patients with acute stroke, with analysis by intention to treat. The publication will follow the approaches published for alteplase.^{57,58}

Table 1. Included trials

Blood pressure profile

Figure 1. Blood pressure during 7 days of treatment. Δ SBP and Δ DBP signify mean difference in systolic and diastolic blood pressure between the two groups; p values were calculated with the independent sample *t* test, and are for difference in systolic blood pressure between groups.

Modified Rankin Scale distribution

Figure 2. Modified Rankin Scale (mRS) at 90 days follow-up. Distribution of mRS scores by treatment group. Comparison by ordinal logistic regression adjusted for baseline factors.

Primary outcome in pre-specified subgroups

Figure 3. Subgroup analysis of effects on functional outcome at 90 days. Pre-defined subgroups are listed in section 4.4.3.

Survival curves

Figure 4. Cumulative hazard of (a) death; (b) recurrence; and (c) cardiovascular events during follow-up. Cox proportional regression with adjustment for baseline covariates, hazard ratio= (95% CI -), p= .
