**ABSTRACT**

Background

Worldwide at least 100 million people are thought to have prevalent cardiovascular disease (CVD). This population has a five times greater chance of suffering a recurrent cardiovascular event than people without known CVD. Secondary CVD prevention is defined as action aimed to reduce the probability of recurrence of such events. Drug interventions have been shown to be cost-effective in reducing this risk and are recommended in international guidelines. However, adherence to recommended treatments remains sub-optimal. In order to influence non-adherence, there is a need to develop scalable and cost-effective behaviour-change interventions.

Objectives

To assess the effects of mobile phone text messaging in patients with established arterial occlusive events on adherence to treatment, fatal and non-fatal cardiovascular events, and adverse effects.

Search methods

We searched CENTRAL, MEDLINE, Embase, the Conference Proceedings Citation Index - Science on Web of Science on 7 November 2016, and two clinical trial registers on 12 November 2016. We contacted authors of included studies for missing information and searched reference lists of relevant papers. We applied no language or date restrictions.

Selection criteria

We included randomised trials with at least 50% of the participants with established arterial occlusive events. We included trials investigating interventions using short message service (SMS) or multimedia messaging service (MMS) with the aim to improve adherence to medication for the secondary prevention of cardiovascular events. Eligible comparators were no intervention or other modes of communication.
Data collection and analysis

We used standard methodological procedures expected by Cochrane. In addition, we attempted to contact all authors on how the SMS were developed.

Main results

We included seven trials (reported in 13 reports) with 1310 participants randomised. Follow-up ranged from one month to 12 months. Due to heterogeneity in the methods, population and outcome measures, we were unable to conduct meta-analysis on these studies. All seven studies reported on adherence, but using different methods and scales. Six out of seven trials showed a beneficial effect of mobile phone text messaging for medication adherence. Dale 2015a, reported significantly greater medication adherence score in the intervention group (Mean Difference (MD) 0.58, 95% confidence interval (CI) 0.19 to 0.97; 123 participants randomised) at six months. Khonsari 2015 reported less adherence in the control group (Relative Risk (RR) 4.09, 95% CI 1.82 to 9.18; 62 participants randomised) at eight weeks. Pandey 2014 (34 participants randomised) assessed medication adherence through self-reported logs with 90% adherence in the intervention group compared to 70% in the control group at 12 months. Park 2014a (90 participants randomised) reported a greater increase of the medication adherence score in the control group, but also measured adherence with an event monitoring system for a number of medications with adherence levels ranging from 84.1% adherence to 86.2% in the intervention group and 79.7% to 85.7% in the control group at 30 days. Quilici 2013, reported reduced odds of non-adherence in the intervention group (Odds Ratio (OR) 0.43, 95% CI 0.22 to 0.86, 521 participants randomised) at 30 days. Fang 2016, reported that participants given SMS alone had reduced odds of being non-adherent compared to telephone reminders (OR 0.40 95% CI 0.18 to 0.63; 280 patients randomised). Kamal 2015 reported higher levels of adherence in the intervention arm (adjusted MD 0.54, 95% CI 0.22 to 0.85; 200 participants randomised). Khonsari 2015 was the only study to report fatal cardiovascular events and only reported two events, both in the control arm. No study reported on the other primary outcomes. No study reported repetitive thumb injury or road traffic crashes or other adverse events that were related to the intervention.

Four authors replied to our questionnaire on SMS development. No study reported examining causes of non-adherence or provided SMS tailored to individual patient characteristics.

The included studies were small, heterogeneous and included participants recruited directly after acute events. All studies were assessed as having high risk of bias across at least one domain. Most of the studies came from high-income countries, with two studies conducted in an upper middle-income country (China, Malaysia), and one study from a lower middle-income country (Pakistan). The quality of the evidence was found to be very low. There was no obvious conflicts of interest from authors, although only two declared their funding.

Authors’ conclusions

While the results of this systematic review are promising, there is insufficient evidence to draw conclusions on the effectiveness of text message-based interventions for adherence to medications for secondary prevention of CVD. Sufficiently powered, high-quality randomised trials are needed, particularly in low- and middle-income countries.

PLAIN LANGUAGE SUMMARY

Text messaging to help people suffering from heart disease adhere to medications

Review question

We reviewed the evidence about the effect of text messaging on medication adherence in people with heart disease. We found seven studies including 1310 participants.

Background

Worldwide, at least 100 million people suffer from heart disease. While there are numerous cost-effective treatments, the majority of these individuals are not taking the medications that they need to keep themselves from suffering more heart problems. One possible method of helping people with heart disease to take their medications is through the use of text message-based reminders.

Study characteristics

Mobile phone text messaging to improve medication adherence in secondary prevention of cardiovascular disease (Review)
The evidence is current to November 2016. We found seven studies that compared using text messages to not using text messages, with follow-up ranging from one month to 12 months.

**Key results**

While the results of these studies appear promising that text messages can help people take their medicines, the studies were small and utilised very different methods and definitions. For that reason, we were not able to compile the findings of the studies. Most of the studies came from high-income countries, and were primarily conducted on men. No studies reported any bad side effects from using text messages. There was no obvious conflicts of interest from authors, although only two declared their funding.

**Quality of the evidence**

The quality of evidence from these studies was very low. Additional high-quality studies on the use of text messages for encouraging people suffering from heart disease to take their medication regularly are needed, particularly in low- and middle-income countries.
### Summary of Findings for the Main Comparison

**Mobile phone text messaging to improve medication adherence in secondary prevention of cardiovascular disease**

**Patient or population:** patients with established arterial occlusive events  
**Setting:** hospital/cardiac rehabilitation facility  
**Intervention:** mobile phone text messaging  
**Comparison:** no intervention or other modes of communication

**GRADE Working Group grades of evidence**

- **High quality:** We are very confident that the true effect lies close to that of the estimate of the effect.  
- **Moderate quality:** We are moderately confident in the effect estimate: The true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.  
- **Low quality:** Our confidence in the effect estimate is limited: The true effect may be substantially different from the estimate of the effect.  
- **Very low quality:** We have very little confidence in the effect estimate: The true effect is likely to be substantially different from the estimate of effect.

---

1. Downgraded one level of evidence due to unclear or high risk of bias for all studies in at least one domain.  
2. Downgraded one level of evidence due to inconsistent reporting of outcome.  
3. Downgraded one level of evidence due to imprecision of the results in one study and different direction of effect in another study.
**BACKGROUND**

**Description of the condition**

Worldwide, there are an estimated 13 million deaths due to coronary heart disease or stroke each year, and 80% of these deaths occur in low- and middle-income countries (Lozano 2012). It is estimated that approximately three times as many people will suffer non-fatal cardiovascular events and that each year 35 million people have an acute coronary or cerebrovascular event. Worldwide, at least 100 million people are thought to have prevalent cardiovascular disease (CVD) (Chambless 1997; WHO 2002; Yusuf 2011). This population has a five times greater chance of suffering a new cardiovascular event than people without known CVD (Kerr 2009).

Secondary CVD prevention is defined as action aimed to reduce the probability of recurrence of a cardiovascular event in patients with known atherosclerotic CVD. There are two main aspects to secondary CVD prevention: risk factor management and medications. Drug interventions (such as antiplatelet therapy, angiotensin-converting enzyme (ACE) inhibitors/ angiotensin receptor blockers (ARBs), beta-blockers and statins) have been shown to be cost-effective in reducing the risk of subsequent fatal and non-fatal cardiovascular events in patients with established atherosclerotic cardiovascular diseases and are recommended in international guidelines (ESC 2012; Smith 2011; WHO 2003a).

Unfortunately there is a well-documented knowledge-practice gap in the implementation of these proven cost-effective interventions. For example, the Prospective Urban Rural Epidemiology (PURE) study reported that in low- and middle-income countries up to 75% of patients with known CVD are not using even one recommended medication (Yusuf 2011). Even in high-income countries, adherence to recommended treatments remains sub-optimal. A cross-sectional survey of 12 European countries showed only 26% of patients on antihypertensives achieving control of hypertension and less than 31% of patients on lipid-lowering medication achieving cholesterol control (Kotseva 2010). It has been shown that a considerable proportion of cardiovascular events could be attributed to poor adherence, with 9% of cardiovascular events in Europe attributed to poor adherence (Chowdhury 2013). It is estimated that good adherence may be associated with a 20% lower risk of CVD and a 35% reduction in all-cause mortality (Chowdhury 2013). This evidence-practice gap might be influenced by different factors, including health system issues such as lack of accessibility and affordability; treatment complexity; or patients' non-compliance with recommendations (Nieuwlaat 2013).

In order to influence non-compliance there is a need to develop scalable and cost-effective behaviour-change interventions. The global number of mobile phone subscribers is estimated at nearly seven billion (ICT 2014). Even in low- and middle-income countries the penetration rate of mobile phones is estimated to be 90% (ICT 2014). The widespread ownership of mobile phones and the possibility of automation leads to a potential to deliver behaviour-change interventions to large numbers of people at low cost. Mobile phone interventions are a potentially promising means to deliver messages to increase medication adherence. The use of mobile devices such as phones to support the delivery of medical care is commonly referred to as mHealth.

**How the intervention might work**

Mobile phone text messages have been shown to improve medication adherence for a variety of conditions including HIV (Sharma 2012). The development of messages should follow some theoretical framework, and text messages should be developed specifically for the target population and intervention (Abroms 2015). Text messages as an intervention are relatively cost-effective and quick, and do not require that the intended audience need to search for information as it is delivered to them (Douglas 2013). Two recent systematic reviews addressed the question of using mobile phones for all types of medication adherence (Anglada-Martinez 2015; Park 2014b). The majority of studies found significant improvement in medication adherence through the use of text messages. Overall, few adverse events have been reported with mobile phone text messaging; however, potential rare adverse effects such as road traffic crashes may occur.

**Why it is important to do this review**

While there is a great deal of enthusiasm for mHealth interventions among researchers and policy makers, there is still limited evidence for its effectiveness (Free 2013). Systematic reviews have recently been conducted on adherence to medications and reported promising results (Anglada-Martinez 2015; Park 2014b; Thakkar 2016); however, to date no systematic review has been conducted evaluating specifically the effect of mobile phone text messaging on secondary CVD prevention. Furthermore, no review has examined how text messages are created, and if short message service (SMS) are tailored based on individual patient characteristics, and if some patients benefit more than others from interventions. Mobile phone text messaging is of particular interest in low- and middle-income countries because of wider accessibility of mobile phones with text-messaging capabilities than smart phones.

**Description of the intervention**

**OBJECTIVES**

Mobile phone text messaging to improve medication adherence in secondary prevention of cardiovascular disease (Review)
To determine whether mobile phone text messaging is effective in enhancing adherence to recommended medication in patients with established arterial occlusive events.

**METHODS**

**Criteria for considering studies for this review**

**Types of studies**
We only included randomised controlled trials (RCTs). We included studies reported as full text, those published as abstract only, and unpublished data.

**Types of participants**
We included participants with established arterial occlusive events, including coronary artery disease, cerebrovascular artery disease, peripheral artery disease, and atherosclerotic aortic disease, for whom antiplatelet, blood pressure lowering medications and lipid-lowering medications are recommended. We included all studies regardless of where the patients were enrolled (community or clinic). We only included studies where at least 50% of participants had established cardiovascular disease (CVD).

**Types of interventions**
We included trials comparing interventions using short message service (SMS) or multimedia messaging service (MMS) to improve adherence to secondary cardiovascular prevention interventions. We compared mobile phone messaging with no intervention, and also with other modes of communication (for example, face-to-face, postal letters, or phone calls). We did not exclude studies based on how the text messages were developed, or if they were one way versus two ways. We only included trials that included adherence, but we also included trials that included both adherence and lifestyle modifications.

**Types of outcome measures**

**Primary outcomes**
1. Adherence to treatment (any definition used in trials)
2. Fatal cardiovascular events
3. Non-fatal cardiovascular events (coronary heart disease (CHD), revascularisation, stroke)
4. Combined CVD event (fatal or non-fatal events)

**Secondary outcomes**
1. Surrogate outcomes according to the different interventions recommended for secondary prevention including low-density lipoprotein (LDL)-cholesterol for the effect of statins, blood pressure for antihypertensive drugs, heart rate for the effect of beta blockers, urinary 11-dehydrothromboxane B2 for the antiplatelet effects of aspirin.
2. Adverse effects including self-reported road traffic crashes and repetitive thumb strain

**Search methods for identification of studies**

**Electronic searches**
We identified relevant studies through systematic searches of the following bibliographic databases on 7 November 2016.
1. Cochrane Central Register of Controlled Trials (CENTRAL, Issue 10 of 12, 2016) in the Cochrane Library
2. MEDLINE in-Process & Other Non-Indexed Citations and MEDLINE (OVID, 1946 to 7 November 2016)
3. Embase Classic and Embase (OVID, 1947 to 4 November 2016)
4. Conference Proceedings Citation Index - Science (CPCI-S) (1990 to 4 November 2016) on Web of Science (Thomson Reuters)
The Cochrane sensitivity-maximising RCT filter was applied to MEDLINE (Ovid) and adaptations of it to the other databases, except CENTRAL (Lefebvre 2011). The search strategies are shown in Appendix 1. We searched all databases from their inception to the present, and imposed no restriction on language of publication. We also conducted a search of ClinicalTrials.gov (www.ClinicalTrials.gov) and the World Health Organization’s International Clinical Trials Registry Platform (ICTRP) (http://apps.who.int/trialsearch/) on 12 November 2016. The search terms used are shown in Appendix 1.

We additionally searched for the clinical trial registry numbers of identified ongoing studies on 14 January 2017 to see if their status had changed and results had been published.

**Searching other resources**
We checked reference lists of all included primary studies and reviewed relevant systematic reviews and meta-analyses (Anglada-Martinez 2015; Chow 2016; de Jongh 2012; Ershad Sarabi 2016; Hamine 2015; Misono 2010; Sahu 2014b; Thakkar 2016; Vodopivec-Jamsek 2012) for additional references.
Data collection and analysis

Selection of studies
Two of four review authors (AJA, LF, NM, NS) independently screened titles and abstracts for inclusion of all identified potential studies and decided to retrieve the full-text copies or to discard them. If there were any disagreements, a third author arbitrated (PP or JPC). We retrieved full-text study reports/publications and two of three review authors (AJA, NM, NS) independently screened the full text and identified studies for inclusion. We resolved any disagreement through discussion. If necessary, a third person (PP or JPC) arbitrated. We identified and excluded duplicates and collated multiple reports of the same study so that each study, instead of the report, is the unit of interest in the review. We completed a PRISMA flow diagram and ‘Characteristics of excluded studies’ table.

Data extraction and management
We used a data collection form to extract study characteristics and outcome data previously piloted on at least one study in the review. Two of three review authors (NM, OO, AJA) extracted study characteristics from included studies. We extracted the following study characteristics.
1. Methods: study design, total duration of study, study setting, withdrawals, and date of study.
2. Participants: number, mean age, age range, gender, condition, diagnostic criteria, smoking history, inclusion criteria, and exclusion criteria.
3. Interventions: intervention, comparison, concomitant medications, excluded medications, how text messages were developed, behaviour-change technique, time from arterial occlusive event, if SMS was personalised.
4. Outcomes: primary and secondary outcomes specified and collected, and time points reported.
5. Notes: funding for trial, and notable conflicts of interest of trial authors.

We resolved disagreements by consensus or by involving a third person (PP or JPC). One review author (AJA) transferred data into the Review Manager 5 (RevMan 2014) file. We double-checked that data were entered correctly by comparing the data presented in the systematic review with the study reports.

Assessment of risk of bias in included studies
Two of four review authors (CT, JM, AJA, NM) independently assessed risk of bias for each study using the criteria outlined in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011). We resolved any disagreements by discussion. We assessed the risk of bias according to the following domains.
1. Random sequence generation.
2. Allocation concealment.
3. Blinding of participants and personnel.
5. Incomplete outcome data.
6. Selective outcome reporting.
7. Other biases including industry funding.

We graded each potential source of bias as high, low or unclear and provided evidence from the study report together with a justification for our judgement in the ‘Risk of bias’ table. We summarised the ‘Risk of bias’ judgements across different studies for each of the domains listed. Where information on risk of bias relates to unpublished data or correspondence with a trialist, we noted this in the ‘Risk of bias’ table.

When considering treatment effects, we took into account the risk of bias for the studies that contributed to that outcome. In addition to routine risk of bias, we also undertook to understand bias in the creation of the SMS. To obtain more information about how the text messages were written, we contacted all authors to request the following information.
1. Is the SMS intervention a reminder?
2. Did the authors describe the process to construct the content of the text messages?
3. Did they evaluate causes for non-adherence in the target population?
4. Were psychological theories used to develop the messages to target the identified behavioural determinants of non-adherence?
5. Were behaviour-change techniques employed to develop the messages?
6. Were different text messages developed according to participants’ characteristics?

Assessment of bias in conducting the systematic review
We conducted the review according to this published protocol and reported any deviations from it in the Differences between protocol and review section of the systematic review.

Measures of treatment effect
We planned to analyse dichotomous data as odds ratios or risk ratios with 95% confidence intervals and continuous data as mean difference or standardised mean difference with 95% confidence intervals. If it had been applicable, we would have entered data presented as a scale with a consistent direction of effect. We would have narratively described skewed data reported as medians and interquartile ranges.

Unit of analysis issues
We did not include any cluster-randomised trials. We did not carry out meta-analysis because of the heterogeneity of the included studies with respect to their methods, population and outcome measures. Therefore, we did not have any unit of analysis issues.
Dealing with missing data
We contacted investigators to verify key study characteristics and obtain missing numerical outcome data where possible (e.g. when a study was identified as abstract only).

Assessment of heterogeneity
The included trials were too heterogeneous in methods, population and outcome measures to pool the data in a meta-analysis. We therefore described the studies narratively.

Assessment of reporting biases
We did not assess reporting bias with a funnel plot as we included only seven studies which were too heterogeneous to pool in a meta-analysis.

Data synthesis
We did not undertake meta-analyses as the included studies were too heterogeneous in their methods, population and outcome measures. Should more studies become available in future updates of this review which enable meta-analyses, we will use a random-effects model as we would still expect some degree of heterogeneity.

'Summary of findings' table
We created a 'Summary of findings' table using the following outcome: adherence to treatment. We used the five GRADE considerations (study limitations, consistency of effect, imprecision, indirectness, and publication bias) to assess the quality of a body of evidence as it relates to the studies for the prespecified outcome. We used methods and recommendations described in Section 8.5 and Chapter 12 of the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011), using GRADEpro software. We justified all decisions to downgrade the quality of studies using footnotes and we made comments to aid the reader's understanding of the review where necessary.

Subgroup analysis and investigation of heterogeneity
We had planned to carry out the following subgroup analyses for the primary outcome.
1. 'The baseline arteriosclerotic cardiovascular' (ASCV) condition (i.e. coronary artery disease, cerebrovascular artery disease, peripheral artery disease, and atherosclerotic aortic disease).
2. Age (non-elderly versus elderly, i.e. 64 or more years old).
3. According to the health system in the population background (universal health systems versus others).
4. Income region (by World Bank income group).
5. Type of setting (private versus public, and rural versus urban).
6. Time of duration of the intervention (less than one year versus one year or more).
7. Time since cardiovascular event (less than one year versus one year to two years versus two years or more).
8. Frequency of text messages (daily versus other).
9. How text messages are developed (theory-based, validated, etc.).
10. If trials are text message only or text message plus phone calls.
11. By different measurements of adherence reported in the articles (for example MARS questionnaire, self-reported, pill recounts, etc.).

However, we were unable to undertake meta-analyses and therefore unable to conduct subgroup analyses. In future updates of this review, when more trials are available, we will re-examine the subgroup analysis.

Sensitivity analysis
We planned to conduct a sensitivity analysis for studies with a low risk of bias. As we were unable to undertake meta-analyses, no sensitivity analysis was done.

Reaching conclusions
We based our conclusions only on findings from the narrative synthesis of included studies for this review. We avoided making recommendations for practice, and our implications for research suggested priorities for future research and outlines the remaining uncertainties.

Results of the search
The search of the databases retrieved 3987 records. The search of the clinical trial registers retrieved an additional 103 records. After de-duplication, 2567 records remained for title and abstract screening which led to the exclusion of 2425 records. Therefore 142 records were assessed as full text. This led to the exclusion of 113 records. Eight studies (16 references) were identified as ongoing and seven studies (13 references) were eligible for inclusion. A search for the clinical trial registry numbers of the eight ongoing studies revealed that three studies are completed but study results are not published yet (NCT01642355; NCT02354040; NCT02783287). One completed study is still classed as ongoing (Chow 2015) as contact with the author revealed that a sub-
analysis for medication adherence is planned. We also identified a published study protocol for one of the remaining ongoing studies (NCT01642355) and added this report. The flow of studies through the process is shown in Figure 1.
Figure 1. Study flow diagram.

7 studies (13 reports) identified as included
8 studies (16 reports) identified as ongoing
Included studies

Details of the methods, participants, intervention, comparison group and outcome measures for each of the studies included in the review are shown in the Characteristics of included studies table.

We included seven studies (Dale 2015a; Fang 2016; Kamal 2015; Khonsari 2015; Pandey 2014; Park 2014a; Quilici 2013), which are heterogeneous in their methods, population and outcome measures. One study (Pandey 2014) was only available as abstracts, and despite attempts to contact the authors we were unable to obtain further information.

Participants

The sample size of included studies ranged from 34 (Pandey 2014) to 521 (Quilici 2013) with a total across all seven studies of 1310, of which 1225 completed follow-up.

All studies included participants with coronary heart disease except Kamal 2015, that reported on stroke. In detail, Dale 2015a included 80% participants with myocardial infarction, 7% with unstable angina and 13% with angina. Two studies included participants with acute coronary syndrome (Khonsari 2015; Quilici 2013), and two studies included participants with myocardial infarction (Pandey 2014; Park 2014a). One study included participants with chronic stable angina (Fang 2016). Participants in one study had undergone coronary stenting for acute coronary syndrome (Quilici 2013). The mean age ranged from 53.6 years (Fang 2016) to 64 years (Quilici 2013). All studies had over 70% males, with the exception of (Pandey 2014) that had 59% males, and Kamal 2015 that had 67.5% males.

Settings

Five studies recruited from hospitals (large metropolitan hospitals (Dale 2015a; Fang 2016), tertiary teaching hospital (Kamal 2015; Khonsari 2015), non-profit community hospital (Park 2014a). One study (Pandey 2014) was set in a cardiac rehabilitation facility. The setting of one study is unknown (Quilici 2013).

Five studies reported the country in which they took place (China (Fang 2016), New Zealand (Dale 2015a), Malaysia (Khonsari 2015), Pakistan (Kamal 2015), USA (Park 2014a)). The countries are not reported for two studies (Pandey 2014; Quilici 2013) but the affiliations of the authors suggest that one took place in France (Quilici 2013) and one in USA (Pandey 2014).

Development of SMS

Authors were emailed about how SMS were created. We were able to obtain responses from four studies (Dale 2015a; Khonsari 2015; Park 2014a; Kamal 2015) the responses are summarised in Table 1.

Two studies reported that the SMS was developed as a reminder to take their medications (Khonsari 2015; Park 2014a), and as a result no work was put into their development.

One study specified that the automated computer program from which the messages were sent was developed particularly for this study (Pandey 2014). Four other studies stated that an automated system was used (Dale 2015a; Kamal 2015; Park 2014a; Khonsari 2015), which can also be assumed for the remaining study but was not explicitly stated (Quilici 2013). In detail, Dale 2015a specified that “we created and refined the Text4Heart intervention through formative and pre-testing studies following the mHealth Development an Evaluation Framework” and “a SMS library of 503 messages has been developed. It is written in English at an appropriate reading level (RMS 800 Lexile: approximately age 13 years) tested using the Lexile Analyzer 2013 software program (MetaMetrics, Durham, NC, USA).” Park 2014a specified that “The primary intervention for this research study was based on Self-Efficacy Theory by Bandura. Briefly, this theory postulates that in one’s capability to successfully perform certain behaviours influences level of motivation, affective states, and action (Bandura 1997).”

No study reported evaluating causes for non-adherence in the study. Dale 2015a and Khonsari 2015 reported on the psychological and behaviour-change techniques used in the development of their text messages (Table 1). Three studies tailored the text messages to the participants’ name (Dale 2015a; Khonsari 2015; Park 2014a). One study stated that the messages were personalised without providing further details (Quilici 2013). One study (Pandey 2014) did not provide information on whether or not the messages were tailored. No study detailed that text messages were tailored to individual patient characteristics. Two studies stated that bi-directional text messaging was required (Dale 2015a; Park 2014a). Participants were required to respond back to confirm receipt (Park 2014a) or send their step count, questions and feedback (Dale 2015a). One study stated that the formulation of the text messages were different every day (Quilici 2013).

Four studies provide details on the template texts used for the text messages (Dale 2015a; Pandey 2014; Park 2014a; Khonsari 2015). Dale 2015a, Kamal 2015, and Khonsari 2015 reported piloting the questionnaires before conducting the study; Fang 2016 did not discuss the method or timing of the SMS at all in the paper.
**Interventions**

Duration of the intervention ranged from 30 days (Park 2014a; Quilici 2013) to 12 months (Pandey 2014). Daily text messages were sent in most studies (Khonsari 2015; Pandey 2014; Park 2014a; Quilici 2013). One study (Dale 2015a) sent daily text messages from week zero to 12 weeks, which were reduced in week 13 to week 24 to five messages a week. One study (Fang 2016) did not report on message frequency. Kamal 2015 stated that they were sent on “preset days of the week”, and at particular times before each medication intake.

The control group was usual care in five studies (Dale 2015a; Kamal 2015; Khonsari 2015; Pandey 2014; Quilici 2013), text messaging for health education in one study (Park 2014a), and monthly phone calls in one study (Fang 2016). Usual care in Dale 2015a consisted of the standard outpatient cardiac rehabilitation program, involving education classes and supervised exercise.

**Outcomes**

All included studies measured adherence to medication. Quilici 2013 looked at aspirin adherence using self-reported adherence. Two studies (Pandey 2014; Khonsari 2015) measured the overall adherence to several prescribed medications. Pandey 2014 included participants on a once-daily regimen of aspirin, a beta-blocker, an angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) and a statin using self-reported logs. Most participants in Khonsari 2015 were on five or more daily medications, adherence was measured using the Morisky Medication Adherence Scale. One study measured adherence to antiplatelet and statin medications separately using both electronic pill bottles and self-reported adherence (Park 2014a). One study only looked at adherence to statins (Fang 2016). One study did not specify which medications the participants were taking and adherence was measured, but specified that it used self-reported medication adherence (Dale 2015a).

One study reported on fatal cardiovascular events (Khonsari 2015).

Two studies provided outcome data for our secondary outcome of blood pressure (Dale 2015a; Kamal 2015) and one study reported on LDL cholesterol (Dale 2015a). Two studies reported on adverse events (Dale 2015a; Quilici 2013).

Four studies did not report on any of our secondary outcomes (Khonsari 2015; Pandey 2014; Park 2014a; Quilici 2013).

**Funding**

The source of funding was reported on in three studies - government body (Dale 2015a), no funding received (Khonsari 2015), and research materials from not-for-profit organisation but for-profit organisation provided use of the mobile Health manager platform (Park 2014a).

**Excluded studies**

Details of excluded studies which most closely missed the inclusion criteria can be found in the Characteristics of excluded studies table.

**Ongoing studies**

We have identified eight ongoing studies (ACTRN12616000422426; Chow 2015; NCT01642355; NCT02336919; NCT02354040; NCT02783287; NCT02883842; NCT02888769). Five are from high-income countries (New Zealand, 330 participants, ACTRN12616000422426; Australia, 710 participants Chow 2015; USA, 400 participants NCT01642355; Canada, 75 participants NCT02336919, and 84 participants NCT02783287), one from a lower middle-income country (Pakistan, 200 participants NCT02354040), and two from an upper middle-income country (China, NCT02883842; NCT02888769). Details can be found in the Characteristics of ongoing studies table.

**Risk of bias in included studies**

Details are provided for each of the included studies in the 'Risk of bias' tables in Characteristics of included studies and in Figure 2 and Figure 3. Overall, studies were assessed as having high or unclear bias across multiple domains, and the quality was deemed to be very low (Summary of findings for the main comparison).
Figure 2. "Risk of bias" graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

- Random sequence generation (selection bias)
- Allocation concealment (selection bias)
- Blinding of participants and personnel (performance bias)
- Blinding of outcome assessment (detection bias)
- Incomplete outcome data (attrition bias)
- Selective reporting (reporting bias)
- Other bias

Legend:
- Low risk of bias
- Unclear risk of bias
- High risk of bias
Figure 3. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Allocation
Four studies reported adequately on the random sequence generation and were therefore judged to be of low risk of bias in this domain (Dale 2015a; Fang 2016; Kamal 2015; Park 2014a). Three studies did not provide enough information and are therefore judged to be unclear risk of bias (Khonsari 2015; Pandey 2014; Quilici 2013). Three studies reported adequately on allocation concealment and were judged to be of low risk of bias in this domain (Dale 2015a; Kamal 2015; Park 2014a). Four studies did not provide enough information and are therefore judged to be unclear risk of bias (Fang 2016; Khonsari 2015; Pandey 2014; Quilici 2013).

Blinding
While blinding of the participants is not possible with this intervention, blinding of outcome assessors could have been done. Two studies (Dale 2015a; Khonsari 2015) clearly state that no blinding occurred and are therefore at high risk of bias. Five studies (Fang 2016; Kamal 2015; Pandey 2014; Park 2014a; Quilici 2013) did not report on this domain and are therefore judged to be of unclear risk of bias.

Incomplete outcome data
Six studies had less than 8% loss to follow-up, comparable in intervention and control group, and were judged to be at low risk of incomplete outcome data. One study had 20% loss to follow-up and was considered to be at high risk of bias (Kamal 2015).

Selective reporting
For two studies we were able to access the trial protocol and all outcomes planned were also reported on (Dale 2015a; Kamal 2015). We therefore judged these studies to be of low risk of reporting bias. One study (Quilici 2013) was judged to be of high risk of bias in this domain as the data were minimal (published as a letter to the editor), and details within the report differed. The other four studies (Fang 2016; Khonsari 2015; Pandey 2014; Park 2014a) are of unclear risk of bias as we did not identify a protocol or trial registry entry to judge reporting bias.

Other potential sources of bias
Two studies were assessed as low risk of bias in this domain as they were funded by a government body (Dale 2015a) and clearly stated that no grant from any type of funding body has supported this trial (Khonsari 2015). Five studies have been judged to be at high (Pandey 2014; Park 2014a; Quilici 2013) or unclear (Fang 2016; Kamal 2015) risk of bias. Pandey 2014 is an abstract publication only and no contact with authors was possible to clarify missing information, the funding source is unclear and differing details are provided in two abstracts. Similarly with Quilici 2013, for which the only source of information is a published letter to an editor in which the outcome data for self-reported non-adherence differs between the text and Figure 2. A for-profit organisation provided use of the mobile Health manager platform in Park 2014a.

Effects of interventions
See: Summary of findings for the main comparison Mobile phone text messaging to improve medication adherence in secondary prevention of cardiovascular disease

Primary outcomes

Adherence to treatment
All seven included studies (1310 randomised participants) reported on medication adherence. Due to the heterogeneity between the studies with respect to participants, methods and outcome measures, we did not pool the results in a meta-analysis but describe the results in narrative form.

Validated Survey measures
Five studies measured medication adherence with the Morisky Medication Adherence Scale (MMAS-8) (Dale 2015a; Fang 2016; Kamal 2015; Khonsari 2015; Park 2014a). MMAS-8 is a patient-reported metric and validated tool that is widely used in adherence research. Unfortunately the studies presented the results in different ways, making it difficult to pool the studies. Dale 2015a, with a follow-up of six months and 116 participants analysed reports for the intervention group a “significantly greater medication adherence score (Mean Difference (MD) 0.58, 95% CI 0.19, 0.97; P=.004)”. In particular, this was a MMAS-8 score of 7.3 (SD 0.9) for the intervention group and 6.8 (SD 1.2) for the control group at the six months follow-up. Fang 2016, had a three-arm design with SMS, SMS + micro letter, or telephone calls (follow-up of six months and 271 patients analysed) reported that participants given SMS alone had reduced odds of being non-adherent compared to telephone reminders (Odds Ratio (OR) 0.40 95% CI 0.18 to 0.63) and patients that had SMS + micro letter had the lowest odds compared to telephone reminders (OR 0.07, 95% CI 0.03 to 0.15). Kamal 2015 (200 participants, two-month follow-up) reported higher levels of adherence in the intervention arm (adjusted MD 0.54, 95% CI 0.22 to 0.85). Khonsari 2015 (62 participants) reported that “the risk of being low adherent
[score 3-8 according to Morisky 1986] among the control group is 4.09 times greater than the intervention group (Relative Risk (RR) 4.09, 95% CI 1.82 to 9.18) at eight weeks follow-up. The same study also reported end of follow-up at two months the low adherence was 16.1% in the intervention group and 58.1% in the control group. Park 2014a, with the shortest follow-up of 30 days and 28 participants analysed in each group, reported a baseline MMAS-8 score of 6.20 (SD 1.66) for the intervention group and 5.85 (SD 2.10) for the control group. At follow-up, the score had risen for both groups, but was higher for the control group at 6.73 (SD 1.49) than for the intervention group at 6.43 (SD 1.22) (no P value reported).

Objective Measures
In addition to the MMAS-8 score, Park 2014a used another measure to test for medication adherence. A Medication Event Monitoring System (opening of the two electronic pill bottles provided a time-stamp corresponding with medication self-administration) resulted in the following. Antiplatelet doses taken on schedule were 86.2% (SD 15.4) in the intervention group and 85.7% (SD 18.2) in the control group. For statins, 84.1% (SD 19.4) of doses were taken on schedule by the intervention group and 79.7% (SD 19.3) in the control group. The correct number of antiplatelet doses taken were 88.0% (SD 14.0) in the intervention group and 87.2% (SD 16.5) in the control group. For statins, 85.4% (SD 16.6) correct number of doses were taken in the intervention group and 81.3% (SD 16.4) in the control group.

Self-Reported Measures
Pandey 2014 assessed medication adherence in 33 participants with self-reported logs at 12 months. This resulted in 90% adherence in the intervention group compared to 70% in the control group (P < 0.0001). At 30 days follow-up, data from Quilici 2013 self-reports differed between the text and Figure 2, but showed a higher adherence in the intervention group (96.4% (text)/97.2% (Figure 2)) than in the control group (93.6% (text)/92.8% (Figure 2). The OR for self-reported aspirin non-adherence as provided in the paper is 0.37, 95% CI 0.15 to 0.90, P = 0.02. The platelet testing confirmed this by showing a 94.8% adherence in the intervention group and 88.8% in the control group. The paper reported the OR for non-adherence as 0.43, 95% CI 0.22 to 0.86, P = 0.01.

Fatal cardiovascular events
One study reported two deaths due to acute coronary syndrome (ACS) complications, both in the control group (Khonsari 2015).

Non-fatal cardiovascular events (coronary heart disease (CHD), revascularisation, stroke)
No study reported this outcome.

Combined cardiovascular disease (CVD) event (fatal or non-fatal events)
No study reported this outcome.

Secondary outcomes

Low-density lipoprotein (LDL)-cholesterol for the effect of statins
One study (Dale 2015a) reported some evidence of a reduction of LDL cholesterol (mmol/L) in the intervention arm (adjusted MD at six months: -0.25, 95% CI -0.49 to 0.01, P = 0.053).

Blood pressure for antihypertensive drugs
Two studies reported on blood pressure. Dale 2015a reported no difference between arms for change in blood pressure (mmHg) (systolic blood pressure adjusted MD at six months 0.09, 95% CI -6.43 to 6.61, P = 0.98; diastolic blood pressure -0.24, 95% CI -3.86 to 3.38, P = 0.90). Kamal 2015 reported a slightly lower mean diastolic blood pressure in intervention group (MD 2.6 mmHg 95% CI -5.5 to 0.15).

Heart rate for the effect of beta blockers
No study reported this outcome.

Urinary 11-dehydrothromboxane B2 for the antiplatelet effects of aspirin
No study reported this outcome.

Adverse effects
No study reported repetitive thumb injury or road traffic crashes or other adverse effects as related to the intervention.

DISCUSSION

Summary of main results
In this review, we were only able to include seven trials with a small number of participants. The seven included trials were small, of variable length (one to 12 months), and heterogenous so we
were unable to pool them for meta-analysis. Six out of the seven trials showed a beneficial effect of interventions of mobile phone text messaging for medication adherence (Dale 2015a; Fang 2016; Kamal 2015; Khonsari 2015; Pandey 2014; Quilici 2013). One trial (Park 2014a), using Morisky Medication Adherence Scale (MMAS-8) showed an improved adherence score for the control group compared to the intervention group. However, this was only one outcome measure in the smallest of the included trials with a short follow-up of 30 days. The other measures used to assess adherence in Park 2014a also showed a beneficial effect of text message reminders. Park 2014a also showed a beneficial effect of reminders compared with education. Only one study reported on fatal cardiovascular events (Khonsari 2015), and they reported two deaths due to acute coronary syndrome (ACS) complications, both of which were reported in the control group. No study reported on any of the other primary outcomes.

Only one study (Dale 2015a) reported on the secondary outcomes of low-density lipoprotein (LDL)-cholesterol, finding a small positive effect on lowering cholesterol. Two studies (Dale 2015a; Kamal 2015) reported no strong evidence of an effect on lowering blood pressure. Four authors replied to our questionnaire on SMS development. No study reported examining causes of non-adherence or provided SMS tailored to individual patient characteristics. No study reported adverse effects that related to the intervention.

**Overall completeness and applicability of evidence**

The evidence of this review is applicable to a predominantly male population aged between 50 to 65 years, with coronary heart (CHD) disease recruited soon after the index event and with a short follow-up, usually less than six months. The studies were mainly on CHD, with only one study examining stroke so the results are not applicable to other cardiovascular diseases.

Two trials for which information on the country is available took place in high-income countries (New Zealand and USA) and two took place in upper middle-income countries (China and Malaysia), and only one was conducted in a lower middle-income country (Pakistan) (Worldbank 2015). It is uncertain where the other two studies were conducted, but they were likely from high-income countries (France and USA). It is therefore unclear whether the results would apply to low- and middle-income countries. Access to mobile phone technology does not seem to be a problem in low- and middle-income countries (Worldbank 2012). We identified eight ongoing studies, that ranged from 75 individuals (NCT02336919) to 710 individuals (Chow 2015). Five of these studies are being conducted in high-income countries (ACTRN12616000422426; Chow 2015; NCT01642355; NCT02336919; NCT02783287).

Most of the studies examined medications and diseases singly, this has implications for the generalisability of results, given that most people may have co-morbidities, or be on multiple medications.

**Quality of the evidence**

Overall the 'Summary of findings' table shows that the evidence is of very low quality. The studies were small, heterogenous and underpowered for the following reasons: Dale 2015a provided a sample size calculation in the trial protocol but the primary outcome was not medication adherence; Quilici 2013 was a 'pilot study'; Park 2014a was reported as 'a convenience sample'. The studies were generally of short duration, with two trials only lasting 30 days.

Each study has at least one risk of bias domain judged as high risk. All studies were either at high or unclear risk of bias for blinding; both performance and detection bias, and only three studies (Dale 2015a; Kamal 2015; Park 2014a) were at low risk for allocation concealment and random sequence generation. Although all studies used mobile phones as the way to deliver the intervention, we identified substantial differences in the actual content of the SMS. Only one study (Dale 2015a) used behaviour-change models to develop the content of the intervention, while two other studies used just "reminders", and for the other two there was lack of information for review authors to judge what type of content was used in the SMS. This heterogeneity not only has implications to the applicability of the evidence, but also raised the questions that quality of reporting for trials evaluating mobile phone interventions is very poor.

**Potential biases in the review process**

We acknowledge that, although systematic searches across a number of resources were conducted, any search has limitations for pragmatic reasons. Publication bias is a known problem for trials with negative results (Hopewell 2009). We tried to overcome this potential limitation by searching clinical trial registries for data on prospectively registered trials. One of the studies was only reported in abstract form (Pandey 2014), and while we attempted to contact the authors on multiple occasions we were unable to obtain further information on this study. Due to the heterogeneity of the identified trials we did not perform a meta-analysis and therefore this review cannot benefit from pooled estimates based on a larger sample size than the individual trials.

**Agreements and disagreements with other studies or reviews**

While there is not a great deal of evidence on mobile text messaging for adherence in secondary prevention, it can be useful to look into research into what has been successful in tackling...
other chronic conditions (for example Viswanathan 2012). Our results are broadly in line with studies in other disciplines that have showed some promising results; particularly in the field of HIV research Anglada-Martinez 2015, a systematic review of 20 generally low-quality studies (7402 participants) of mhealth for adherence to HIV medications found a great deal of heterogeneity, but reported 65% of studies reported a positive effect of mhealth on adherence. Another systematic review (Devi 2015) that included mHealth on adherence to medications found 70% (33 of 47) of studies reported positive effects. Al-Gammi and colleagues conducted a systematic review looking at cardiovascular medication adherence in cardiac patients, and also found too much heterogeneity of results to conduct meta-analysis (Al-Gammi 2016). In a large systematic review of mHealth for behaviour-change and disease management, Free 2013 found that text message-based interventions increased adherence to antiretroviral (ART) and smoking cessation. One study on mobile text messaging for adherence on all chronic diseases found that mobile text messaging nearly doubled the odds of medication adherence (Thakkar 2016). Our study is the first review to include an assessment of SMS development.

AUTHORS’ CONCLUSIONS

Implications for practice

While the studies suggested positive effects of mobile text messaging for adherence to medications, the findings are of very low quality, and we were unable to conduct meta-analysis. As a result we have very little confidence in the findings, and cannot make recommendations for practice.

Implications for research

Mobile text messaging appears to have positive effects on adherence to medications for secondary prevention of cardiovascular disease (CVD), with very little evidence of adverse events. However, there is a lack of high quality evidence. Although we were able to identify eight ongoing studies, most of these are from high-income countries. As a result we call for more, adequately powered, good quality, randomised studies to be conducted, particularly in low-resource settings. Because in most cases there is a need for lifelong adherence to medications longer-term trials are also needed. Future studies should also examine the frequency and timings that the messages should be sent; message content; optimal development processes, and process evaluations to assess the mechanisms by which messages have effect. It is of particular importance that standardised approaches to measure adherence (development of free and validated scores) are used so that outcomes can be pooled across studies.

ACKNOWLEDGEMENTS

We are grateful to Deirdre Beecher for her help with the assessment of one Italian paper (Capomolla 2005) and to Marina Karanikolos with the assessment of one Russian paper (Kiselev 2011).

CHARACTERISTICS OF STUDIES

Characteristics of included studies  [ordered by study ID]

Dale 2015a

| Methods | Design: two-arm, parallel RCT  
| Setting: two large metropolitan hospitals, Auckland, New Zealand  
| Recruitment period: over 10 months between 2013 and 2014  
| Length of intervention: 6 months  
| Two-arm, parallel, RCT |

| Participants | Inclusion criteria: “Included participants were English-speaking adults with a documented diagnosis of CHD (myocardial infarction, angina, or revascularization). [...] access to the Internet was a requirement. [...] phones were supplied for the duration of the study if necessary.”  
| Exclusion criteria: “Those with untreated ventricular tachycardia, severe heart failure, life-threatening coexisting disease with life expectancy less than 1 year, and/or significant exercise limitations for reasons other than CHD were excluded.”  
| Randomised: n = 123, n = 61 intervention, n = 62 control group  
| Number available for follow-up: n = 57 intervention (n = 2 withdrew due to medical reasons, n = 2 withdrew due to being too busy), n = 59 control (n = 3 could not be contacted)  
| Mean age in years (SD): 59.9 (11.1), intervention group: 59.0 (10.5), control group: 59.9 (11.8)  
| Sex (% male): 81.3, intervention group: 79, control group: 84 |

| Interventions | “All participants received usual care, which included inpatient rehabilitation and encouragement to attend center-based CR. Traditional CR offered at the hospital recruiting sites in this study consisted of one 1-hour outpatient education program per week for 6 weeks at a hospital or community center covering a range of topics, including cardiovascular risk factors, lifestyle change, and psychosocial support. Patients also were encouraged to attend a 16-session supervised exercise program at the participating hospital or outpatient center. Participants could take part in usual care CR from point of discharge to 6 months after their heart event.”  
| “All participants were telephoned at 3-months postrandomization to collect primary outcome data. [...] At 6-months postrandomization, participants were seen at a clinic or in a home setting for final follow-up assessment.”  
| Intervention group: “In addition to usual care, the intervention group received a 24-week mHealth program sent by automated daily text messages and access to a supporting website commencing within a week of the baseline assessment. [...] Messages were tailored to participants’ name and preferred time of day to receive messages. From weeks 13 to 24, the frequency of messages decreased to 5 per week. Bidirectional messaging was used because participants were prompted to text in their weekly pedometer step counts and to ask questions or for feedback on other behaviors.”  
| Text type: automated, bidirectional  
| Control group: usual care as describe above |
### Outcomes

**Primary outcome:** adherence to recommended health guidelines measured as a binary variable using a self-reported composite health behavior score based on the European Prospective Investigation into Cancer (EPIC)-Norfolk Prospective Population Study at 6 months (smoking status, physical activity, alcohol consumption, fruit and vegetable intake)

**Secondary outcomes:** biomedical risk factors (systolic and diastolic blood pressure, lipid profile, weight, BMI, waist-hip-ratio) and subsequent CHD risk probability, medication adherence was measured using the Morisky 8-item Medication Adherence Questionnaire, serious adverse events, hospital anxiety, hospital depression, overall self-efficacy, overall illness threat, engagement in the intervention

**Medication adherence:** at 6 months: intervention group 7.3 (0.9), control group 6.8 (1.2), adjusted mean difference 0.58, 95% CI 0.19 to 0.97

**Blood pressure (mmHg) mean (SD):** systolic: intervention group: 131 (17) at baseline, 136 (20) at 6 months, control group: 129 (26) at baseline, 135 (16) at 6 months, adjusted mean difference at 6 months -0.09 (-6.43 to 6.61); diastolic: intervention group: 78 (11) at baseline, 79 (11) at 6 months, control group: 75 (11) at baseline, 79 (10) at 6 months, adjusted mean difference at 6 months -0.24 (-3.86 to 3.38)

**LDL cholesterol (mmol/L) mean (SD):** intervention group: 2.7 (1.3) at baseline, 1.7 (0.6) at 6 months, control group: 2.4 (1.0) at baseline, 1.9 (0.8) at 6 months, adjusted mean difference at 6 months -0.25 (-0.49 to 0.01)

**Serious adverse events:** n = 8 intervention group, n = 5 control group ("although none were study related")

### Notes

**Funding:** Government body (National Institute for Health Innovation, the University of Auckland)

### Fang 2016

**Methods**

- **Design**: three-arm, parallel RCT (arm 1: SMS, arm 2: SMS + Micro letter, arm 3: phone)
- **Setting**: Chengdu City, China
- **Recruitment period**: over 10 months in 2013
- **Length of intervention**: 6 months

**Participants**

- **Inclusion criteria**: adult patients with CAD treated in the General Medicine Department at West China Hospital. All patients had chronic stable angina consistent with criteria of the Chinese Medical Association of Cardiovascular Disease Guide
- **Exclusion criteria**: (1) nonconformance with the diagnostic standards for chronic stable angina established by the Chinese Medical Association of Cardiovascular Epidemiology, (2) history of mental illness, (3) infection, fever, operation, serious heart failure, respiratory failure or acute stroke in the prior month and (4) inability to use a mobile phone that accepts SMS
- **Randomised**: n = 280, arm 1: 95, arm 2: 92, arm 3: 93
- **Number available for follow-up**: n = 271. Nine withdrew for either unwillingness to complete (6) personal issues (3) arm 1 n = 4, arm 2 n = 2, arm 3 n = 3
- **Mean age in years (SD)**: arm 1 = 53.73 (7.20), arm 2 = 53.69 (7.74), arm 3 = 53.50 (7.62)
- **Sex (% male)**: arm 1 = 70.33, arm 2 = 67.78, arm 3 = 67.78
- **Disease duration (average years)**: arm 1 = 3.02 years, arm 2 = 2.98 years, arm 3 = 2.94

**Interventions**

All patients received initial questionnaires at the hospital. The SMS group received medication reminders and educational materials via SMS. The SMS + Micro Letter group received medication reminders via SMS and educational materials via ML. We built a public ML platform, from which we regularly released CAD-related information, including the hazards and methods of preventing hyperlipidaemia, the role, scope, usage, method of use, and side effects of lipid-lowering drugs and other related information. Patients in the SMS + ML group had open access to all information on the ML platform. The phone group received a telephone call once a month to remind them of their medication schedule and upcoming appointments. After six months, we compared statin prescription adherence among the three groups

**Text type**: Not stated

**Outcomes**

- **Primary outcome**: adherence to statin medication using the Morisky Medication Adherence Scale (MMAS)
- **Medication adherence**: at baseline: Arm 1 2.88 (0.71), Arm 2 2.86 (0.71), Arm 3 2.86 (0.87), at six months: Arm 1 (SMS only compared to phone) OR 0.40 (0.18, 0.63)
Kamal 2015

Design: two-arm, parallel RCT  
Setting: Karachi, Pakistan  
Recruitment period: not stated  
Length of intervention: 2 months

Inclusion criteria: age greater than 18 years old; history of stroke(s) confirmed by neuroimaging at the time of the episode; more than 1 month since last episode of stroke; use of at least two drugs such as (but not limited to) antiplatelets, statins, antihypertensives to control risk factors of stroke; modified Rankin Score of 3 or less (so that they are able to operate mobile phones); possession of a personal cell phone that the patient has access to at all times. In the case of patients who do not own or are unable to use mobile phones, they must have a caregiver available at all times who possesses a cell phone; ability to receive, comprehend and reply to an SMS in English, Nastaleeq Urdu (local Urdu script) or Roman Urdu. In the case of patients who themselves are unable to receive, comprehend or reply to an SMS, they must have caregivers available at all times who could perform the above mentioned tasks

Exclusion criteria: biological impairment in reading or responding to SMS in the caregiver such as (but not limited to) loss of vision, visual field cuts, aphasia in case the patient
### Kamal 2015 (Continued)

- himself/herself is supposed to receive SMS; Diagnosed organ dysfunction or malignancy such as hepatic, renal or malignancy; plans to travel outside the country inside the two months following enrolment  
  - **Randomised:** $n = 200$. Intervention = 100, control = 100  
  - **Number available for follow-up:** $n = 162$. Intervention arm: 17 lost to follow-up: 10 unwilling to come, 2 sick, 3 out of station 2 discontinued intervention. Control arm: 21 lost to follow-up: 17 unwilling to come, 4 out of station  
  - **Mean age in years (SD):** Control: 57.6 (1.3), intervention: 56 (1.5)  
  - **Sex (% male):** 67.5 % male (64% in control 71% in intervention)  
  - **Disease duration:** at least one month

### Interventions

- **Intervention:** In addition to the usual care, intervention group received automated SMS reminders customised to their individual prescription. The participants were required to respond to the SMS stating if they have taken their medicines. Moreover, twice weekly health information SMS were also sent to the intervention group. Health information SMS were customised according to medical and drug profile of every patient by the research team.  
  - **Control:** patients received the usual standard of care provided at the centre for stroke patients. This primarily consisted of regular follow-up visits (as advised by their neurologist) with their stroke neurologist. In general, these were at 1, 3, 5, 9, 12 months after a stroke. Each patient was provided with a telephone number that could be used to reach the stroke team in case of an emergency and each patient was also reminded of their clinic appointments 1-2 days prior via SMS and/or phone.  
  - **Text type:** automated- two-way  
  - "The messages were designed in a weekly schedule at preset days of the week for total 8 weeks e.g., Wednesday and Saturday week 1 for patient X. The timings were decided according to the prescription so that health messages do not collide with the reminder messages for that day. Usually 5 pm was found feasible for most participants. These messages did not ask for a reply. These health information SMS were codified by Michie’s Taxonomy of Behavioural Change for repeatability”

### Outcomes

- **Primary outcome:** Change in medication adherence after 2 months using the Morisky Medication Adherence Scale (MMAS)  
  - **Secondary Outcome:** Change in blood pressure, acceptability of SMS  
  - **Medication adherence:**  
    - at baseline:  
      - Control 6.6 (0.17) Intervention 6.6 (0.16)  
    - at two months:  
      - Control 6.7 (1.32) Intervention 7.4 (0.93)  
      - Adjusted mean difference (adjusted for baseline, number of pills, dosing frequency, age, gender, employment status, education, use of alarms)  
        - 0.54 (95% CI 0.22, 0.85)  
  - **Blood pressure:**  
    - The mean diastolic blood pressure in the intervention group was 2.6 mmHg (95 % CI; −5.5 to 0.15) lower compared to the usual care group  
  - **Serious adverse events:** Not discussed

### Khonsari 2015

**Methods**
- **Design:** prospective, parallel, two-arm
- **Setting:** tertiary teaching hospital In Kuala Lumpur, Malaysia
- **Recruitment period:** 23 January 2013 to 23 February 2013
- **Length of intervention:** 8 weeks

**Participants**
- **Inclusion criteria:** ACS
- **Exclusion criteria:** no cell phone to receive text messages; were not discharged during the specified study timeline or were discharged to a care facility or transferred to another health care institution; were illiterate or unable to read text messages; were not available for the two-month period of the study (including being unavailable by phone and/or travelling out of the country); or had been diagnosed with cognitive impairment so that the informed consent process might be incomprehensible
- **Randomised:** n = 62, n = 31 intervention group, n = 31 control group
- **Number available for follow-up:** n = 31 intervention group, n = 29 control (n = 2 death)
- **Mean age in years:** intervention (56), control (59)
- **Sex (%) male:** intervention (87.1), control (83.9)
### Interventions

**Intervention group:** The participants randomised to the intervention group received text-message reminders based on the following template before every medication intake, starting the day after discharge: “[Mr/Ms] [Patient’s Name], please take [Medication Quantity] tablet of [Medication Name] at [Time]”. When the course of medication was completed (patients were given a 30-day dosage), a message was sent to remind the patients to come to the hospital and have their prescribed cardiac medications refilled. The SMS reminder service was continued until two months after discharge. The system is a web-based software where all tasks are handled automatically. Reminders were generated and sent to each participant in the intervention group before every cardiac medication intake in an 8-week programme. The researcher also followed up with the participants in the SMS group via telephone calls once per two weeks during the study to reassure the delivery of text messages, to enquire whether any emergency readmission was needed as well as to show up for their appointments

**Text type:** Automated, one-way

**Control group:** Usual care for ACS post-discharge including cardiac rehabilitation and follow-up appointments with the cardiologist, usually occurring at six or eight weeks following discharge

### Outcomes

**Primary outcome:** medication adherence, measured with eight-item Morisky Medication Adherence Scale (MMAS-8-item)

**Secondary outcomes:** NYHA classification, death, hospital readmission rates, patient’s perception on the automated short message service

**Medication adherence:** intervention (64.5% (n = 20) high adherence; 16.1% (n = 5) low adherence); control (12.9% (n = 4) high adherence; 58.1% (n = 18) low adherence) ; risk of being low adherent among the control group is 4.09 times greater than the intervention group (RR = 4.09, 95%CI 1.82 to 9.18)

**Death:** intervention (n = 0); control (n = 2) due to ACS complication

### Notes

**Funding:** “This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.”

### Pandey 2014

#### Methods

- **Design:** prospective, parallel, two-arm
- **Setting:** cardiac rehabilitation facility, country not reported
- **Recruitment period:** not reported
- **Length of intervention:** 12 months

#### Participants

- **Inclusion criteria:** recently discharged after MI who were receiving care at a single cardiac rehabilitation facility; had to be on a once daily regimen of aspirin, a beta-blocker, an ACE or ARB and a statin
- **Exclusion criteria:** patients without cell phones and those unable to provide informed consent in English were excluded
- **Randomised:** n = 34, not separately reported for intervention and control group
- **Number available for follow-up:** n = 1 dropout of control group, no reason
- **Mean age in years:** total (63 in Pandey 2014, 64 in Pandey 2015), not separately reported for intervention and control group
- **Sex (% male):** total (59% in Pandey 2014, 64% in Pandey 2015), not separately reported for intervention and control group

#### Interventions

- **Intervention group:** daily text message reminders at the times they were to take their prescribed medication; “Please take your morning medication now” and indicated which medication they should take at that time
- **Text Type:** automated
- **Control group:** usual care
Outcomes

Primary outcome: medication adherence 12 months after randomisation assessed with self-reported logs.

Medication adherence: intervention (month 1 = 98%, month 12 = 90%); control (month 1 = 92%, month 12 = 70%)

Notes

Funding: not reported.

Publication: Published abstracts only (two different abstracts published with some differing information. Authors contacted on multiple occasions to clarify data, but have not responded).

Park 2014a

Methods

Design: prospective, parallel, three-arm
Setting: non-profit community hospital, Northern California, USA
Recruitment period: April 2012 to March 2013
Length of intervention: 30 days
### Participants

**Inclusion criteria:** ≥ 21 years of age, hospitalised for non-ST elevation MI, ST elevation MI or PCI, prescribed an antiplatelet medication (thienopyridine class of ADP receptor inhibitors and/or a cyclooxygenase inhibitor (i.e. aspirin), prescribed a statin medication (HMG-CoA reductase inhibitors), owned a mobile phone with text messaging capability and were able to speak, read, and understand English

**Exclusion criteria:** cognitive impairment that limited ability to understand and complete questionnaires, and inability to operate a mobile phone

**Randomised:** n = 90 total, n = 30 intervention group 1, n = 30 intervention group 2, n = 30 control group

**Number available for follow-up:** n = 84, n = 28 intervention group 1 (n = 2 lost to follow-up, withdrew due to illness), n = 28 intervention group 2 (n = 2 lost to follow-up, of which n = 1 withdrew due to busy schedule and n = 1 withdrew due to illness), n = 28 control group (n = 2 lost to follow-up, of which n = 1 due to privacy request and n = 1 was unable to contact)

**Mean age in years (SD):** 59.2 total, 58.2 (10.6) intervention group 1, 58.3 (8.5) intervention group 2, 61.1 (9.1) control group

**Sex (% male):** 76 total, 76.7 intervention group 1, 66.7 intervention group 2, 83.3 control group

### Interventions

**Intervention group 1:** text messages for medication reminders and health education; The medication reminders were two-way, requiring patients to respond back to confirm receipt. They were delivered, twice daily, at times selected by the patients that correlated with their medication schedule. An example of a medication reminder was, “John, take Plavix 75 mg at 9:00 AM. Respond with 1.”

**Intervention group 2:** text messages for health education; health education messages were one-way educational health messages on cardiovascular risk reduction on Monday, Wednesday, and Friday at 2 PM

**Text type:** sent from a customisable program through CareSpeak Communications “mobile Health manager” platform (New Jersey), two-way

**Control group:** no text messages

For the purpose of the review, the two intervention arms were compared - intervention group 1 (intervention), intervention group 2 (control)

### Outcomes

**Primary outcome:** medication adherence, measured by Medication Event Monitoring System (opening of he two electronic pill bottles provided a time-stamp corresponding with medication self-administration), responses to messages and MMAS-8, a self-report measure completed at baseline and follow-up

**Secondary outcomes:** feasibility and patient satisfaction, assessed by successful execution of the intervention, patient participation, and by the Mobile Phone use Questionnaire (developed for this study)

**Medication adherence:**

- MEMS, per cent (SD) doses taken on schedule in % (SD) (antiplatelets): Intervention group (analysed n = 24): 86.2 (15.4), control group (analysed n = 19): 85.7 (18.2)
- MEMS, per cent (SD) doses taken on schedule in % (SD) (statins): Intervention group (analysed n = 24): 84.1 (19.4), control group (analysed n = 20): 79.7 (19.3)

- responses to messages, mean response rate in % (SD) (antiplatelets): M = 90.2 (9)
- responses to messages, mean response rate in % (SD) (statins): M = 83.4 (15.8)

- MMAS-8 score (SD): intervention group (analysed n = 28): baseline 6.20 (1.66), follow-

RCT: randomised controlled trial

**Characteristics of ongoing studies  [ordered by study ID]**

**ACTRN12616000422426**

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>Text4Heart Partnership</th>
</tr>
</thead>
</table>
| Methods                     | **Design**: Prospective, parallel RCT  
**Setting**: Auckland, New Zealand |
| Participants                | **Expected**: 330  
**Inclusion criteria**: Aged 18-80, A documented diagnosis of an acute coronary syndrome (including myocardial infarction [MI], unstable angina) or percutaneous coronary revascularisation procedure, are 18 years or older, eligible for cardiac rehabilitation  
**Exclusion criteria**: Untreated ventricular tachycardia, severe heart failure, life threatening co-existing disease with life expectancy < 1 year, and significant exercise limitations other than cardiovascular disease |
| Interventions               | **Intervention**:Each participant in the intervention group will receive at minimum the basic heart health CR program, consisting of 5 messages per week for 6 months. The general heart health messages provide overall advice and support on undertaking lifestyle change, including, taking medication, being physically active, eating healthy, and reducing alcohol consumption. One message per week on each topic is delivered for the entire six months  
**Control group**: Participants in the control arm will be offered the standard outpatient CR programme provided by each hospital, which involves support and education provision to discharged patients, with supervised exercise offered at all three participating hospitals for those wishing to participate (Phase 2 CR usually of 6-12 weeks duration). During Phase 3, participants are encouraged to continue with their lifestyle changes and join a cardiac club. Heart Guide Aotearoa is also offered at the discretion of cardiac nurses. Given the proven effectiveness of CR, it would be unethical not to offer usual CR to all participants; therefore the Intervention arm participants will be advised that they are able to access the usual CR programme in addition to the mHealth intervention, if they wish to do so |
| Outcomes                    | **Primary outcome**: Proportion of participants adhering to medication at 24 weeks. The medication adherence measure in this trial will be prescription record-assessed adherence, defined as: a dispensed medication ratio of 80% for each of the classes of medications consistent with guideline recommended therapy (e.g., antiplatelet, ...

### Chow 2015

#### Trial name or title
Tobacco, EXercise and dieT MEssages (TEXT ME): The effect of a semi-personalised lifestyle reminder text message intervention on cardiovascular risk factors in patients with cardiovascular disease and those who are at high risk of cardiovascular disease

#### Methods

| Design: | prospective, parallel |
| Setting: | large tertiary referral centre and university teaching hospital in Sydney, Australia |
| Follow-up: | six months |

#### Participants

| Inclusion criteria: | older than 18 years, had documented CHD, and were able to provide informed consent. CHD defined as documented prior MI, coronary artery bypass graft surgery, PCI or 50% or greater stenosis in at least 1 major epicardial vessel on coronary angiography |
| Exclusion criteria: | did not have an active mobile phone or sufficient English language proficiency to read text messages |
| Randomized: | 710 randomised, n = 352 intervention group, n = 358 control group |
| Number available for follow-up: | n = 319 analysed in intervention group (n = 7 requested to stop, n = 4 died during intervention period, n = 2 unable to contact at 6 months follow-up, n = 20 excluded due to missing LDL-C measures at baseline, 6 months or both), n = 333 analysed in control group (n = 3 unable to contact at 6 months, n = 1 died prior to 6 months follow-up, n = 21 excluded due to missing LDL-C measures at baseline, 6 months or both) |
| Mean age in years (SD): | 59 (41-75) |
| Sex (% male): | |

#### Interventions

| Both groups received 3 study management text messages providing them with their allocation assignment, study contact details, and a reminder prior to the follow-up appointment |
| Intervention group: | Participants received, in addition to usual care, the 6-month prevention program of approximately 96 messages. Four text messages per week about medicines, general health information, diet, physical activity and smoking cessation (where applicable). Text messages were semi-personalised (addressed to participant’s preferred name). Each message was sent on 4 to 5 randomly selected weekdays and arrived at random times of the day during working hours. The message management program selected messages for each participant at random from a bank of messages. Participants were told not to respond to messages |
| Control group: | Control participants received usual care, which generally included community follow-up with the majority referred to inpatient cardiac rehabilitation, as determined by their usual physicians |

### NCT01642355 (Continued)

**Outcomes**

**Primary Outcome Measures:** Reduction of Non-HDL cholesterol [Time Frame: 6 months]

**Secondary Outcome Measures:**
- Lipids [Time Frame: 6 months] - LDL-C, HDL, triglycerides
- Physical Activity [Time Frame: 6 months] - Yale Physical Activity assessment (Part 2)
- Nutrition [Time Frame: 6 months] - Northwest Lipid Research Clinic (NWLRC) Fat Intake Score and fruit and vegetable assessment questions
- Medication Adherence [Time Frame: 6 months] - Morisky-4 medication adherence survey
- Optimal medical regimen [Time Frame: 6 months] - assessment of lipid-lowering and cardiovascular medication regimen
- Quality of life [Time Frame: 6 months] - Euro Qual 5D survey
- Smoking cessation [Time Frame: 6 months] - Patient-based Assessment and Counseling for Physical Activity and Nutrition (PACE) smoking assessment
- Cardiovascular risk [Time Frame: 6 months] - cardiovascular risk assessment score (i.e. Framingham)
- Cardiovascular events [Time Frame: 5 years] - cardiovascular events and hospitalisations reported by phone call follow-up to 5 years

**Starting date**

June 2012

### NCT02336919

**Trial name or title**

The use of texting messaging to improve the hospital-community transition and prevent readmission in patients with cardiovascular disease (Txt2Prevent)

**Methods**

Randomised efficacy study with parallel assignment
- Masking: Single-blind (Investigator)

**Study location:** Canada

**Participants**

**Estimated enrolment:** 75

**Inclusion criteria:**
- Are acute coronary syndrome patients on the non-surgical ward who will be discharged home
- Own a phone with text-messaging capabilities and have the ability to access new text messages
- Have the ability to provide informed consent
- Have the ability to read and understand English

**Interventions**

In addition to usual discharge treatment, the intervention arm will receive instructions and information for acute coronary syndrome patients as well as the Txt2Prevent text-messaging program. The program will include a variety of topics such as standard follow-up care reminders as well as general self-management and healthy living texts. There will be two streams, one for current/recent smokers and one for non-smokers. Texts will be sent out every 1-3 days for 60 days. All participants in the same stream will receive the same texts in the same order.
### NCT02336919 (Continued)

| Outcomes | Primary Outcome: Self-management  
Secondary Outcomes: Medication adherence, health-related quality of life, hospital readmissions, mortality |

### NCT02354040

<table>
<thead>
<tr>
<th>Trial name or title</th>
<th>TalkingRx</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods</td>
<td>Randomised parallel arm study</td>
</tr>
</tbody>
</table>
| Participants | Estimated enrolment: 200  
Inclusion criteria:  
- Adult men and women, 18 years old  
- Ischaemic stroke or CAD, which is stable and outpatient-based  
- Own cell phone |
| Interventions | Study conducted in Pakistan. Assigned to receive Health Literacy and Reminder Updates via the IT-based intervention TalkingRx, in addition to Usual Care for patients in the intervention group. The physician-written prescription for antiplatelets and statins will be transferred on an OMR sheet and will be scanned. The information on the prescription (dose, name of the medication, duration, route or any other special instruction) will be sent to the patients via a text and a voice SMS (in Urdu language). The patients also receive an individualised code that helps them request for repeated reminders for their medication timings. However, a weekly medication reminder SMS will be sent to the patients in the intervention arm |
| Outcomes | Primary outcome: Medication adherence  
Secondary outcome: Health literacy |
| Starting date | March 2015 |
| Contact information | Dr. Ayeesha Kamran Kamal, Aga Khan University, Karachi, Pakistan |
| Notes | The study has been completed but no study results were available at the time of search |
**Trial name or title**
The impact of text messaging on medication adherence and exercise regimen among post-myocardial infarction patients

**Methods**
**Design:** Parallel randomised control trial  
**Setting:** Cambridge Cardiac Rehabilitation in Ontario, Canada

**Participants**
84 participants aged 18 years and older  
**Inclusion Criteria:**  
- Post-MI hospital discharge within 2 weeks  
- Enrolled in cardiac rehabilitation  
- Prescribed antiplatelets, beta-blockers, ACE-inhibitors or ARBs, and/or statins on 1x/day regimen (for medication adherence trial)  
- Prescribed exercise regimen (for exercise trial)  
- Ability to read and write English  
- Possession of a cell phone with text messaging capability  
**Exclusion Criteria:**  
- Age < 18  
- Incarcerated individuals  
- Unable to read and write English  
- Not in possession of a cell phone  
- Patients prescribed medication regimen > 1x/day

**Interventions**
2 trials: medication adherence and exercise adherence  
**Intervention**  
Text message reminder for medication adherence  
Patients randomised to this arm receive one text message per day (at the scheduled time) reminding them to take their medication control:  
Usual care for medication adherence.

**Outcomes**
**Primary Outcomes:** Medication adherence (Time Frame: 12 months), Exercise frequency (Time Frame: 12 months)  
**Secondary Outcomes:** Exercise duration (Time Frame: 12 months), Full medication adherence (Time Frame: 12 months)

**Starting date**
January 2012

**Contact information**
Niteesh K Choudhry, MD, PhD Brigham and Women's hospital

**Notes**
This study has been completed but no results were available at the time of search. This study was sponsored by Brigham and Women's Hospital, Boston, Massachusetts

</tbody>
</table>
Table 1. SMS development (Continued)

| Evaluation of causes for non-adherence | No | According to the study method, patients were recruited during an admission for ACS prior to discharge from the cardiology ward. It means that all patients were primarily diagnosed with ACS without any experience of taking cardiac medications. Therefore, evaluating causes for non-adherence in the target population was not applicable. | No information | - | No information | - |

| Used psychological theories to develop SMS | Messages were based on social cognitive theory and the common sense model (Dale 2014b) | The WHO multidimensional adherence model (WHO 2003b) that guided this study included many different aspects to describe medication non-adherence behaviour including psychological factors. | No Information | - | No information | - |
### Table 1. SMS development (Continued)

| Used behaviour-change techniques to develop SMS | Yes - All messages were coded according to their theoretical construct and corresponding BCT | Development of the automated SMS reminder system in this study was useful for deploying spaced repetition strategies via text messaging. Basically, spaced repetition strategy posits that instruction which is repeated at intervals have a great impact on | No information | - | No information | - |

It is emphasised that no single determinant is responsible for non-adherence to treatment because the adherence phenomenon is multidimensional and results from the interplay of five sets of factors (dimensions) including:

A. Social and economic factors,
B. Therapy-related factors,
C. Condition-related factors,
D. Healthcare team and system-related factors and
E. Patient-related factors.
Table 1. SMS development (Continued)

| SMS designed according to participants characteristics | No, but participants could pick messages on the health behaviour they were most interested in changing (Physical activity, healthy eating, smoking cessation, or stress management). Messages were also personalised with participant’s preferred name. | No | No information | - | No information | - |

| Pilot phase to evaluate clarity, grammar of SMS | Yes, we pilot tested the healthy eating messages. Feedback from participants was used to refine the messages (Dale 2014a) | We piloted the intervention with a sample size of ten cardiac patients during the first stage of the study. During this phase, a variety of test scenarios and clarity of SMS content were analysed and, consequently, the required changes and fixes were applied in order to achieve the desired functions. | No | information | - | No information | - |

1Text in italics = communication from authors
CONTRIBUTIONS OF AUTHORS

The first (AJA) and second (NM) author contributed equally to the review.
AJA: screening, data extraction, writing of review, ‘Risk of bias’ assessment.
NM: searches, screening, data extraction, ‘Risk of bias’ assessment, ‘Summary of findings’ table with GRADE, writing of review.
JM: ‘Risk of bias’ tables.
CT: ‘Risk of bias’ tables.
OO: Screening, data extraction.
CF: Reviewed manuscript, advised on text messaging interventions
NS: screening, extraction and consulting on design and methods.
JPC: arbitration of disagreement, consulting on design and methods.
PP: proposal, writing, arbitration of disagreement, consulting on design and methods.

DECLARATIONS OF INTEREST

AJA: nothing to declare.
NM: nothing to declare.
JM: nothing to declare.
CT: has collaborated with Bristol Myers Squibb and Pfizer to provide expert testimony and lectures. These have been unrelated to the subject matter of this review.
OO: nothing to declare.
CF: I am a co-applicant on a global health MRC UK grant and have worked on the development of interventions for Colombia and the UK on the topic of SMS as intervention to improve adherence to medications in secondary prevention of cardiovascular disease.
NS: nothing to declare.
JPC: I am a co-applicant in two grants (one from UK and one from Colombia) in the topic of SMS as intervention to improve adherence to medications in secondary prevention of cardiovascular disease.
PP: I am the principal investigator for a study developing and piloting an mHealth intervention to increase adherence for cardiovascular secondary prevention interventions.

SOURCES OF SUPPORT

Internal sources
• No sources of support supplied
External sources

- This project was supported by the National Institute for Health Research via Cochrane Infrastructure funding to the Cochrane Heart Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health, UK.

Differences between protocol and review

Due to the heterogeneity between the studies with respect to participants, methods and outcome measures, we did not pool the results in a meta-analysis but describe the results in narrative form.
