

A qualitative study of trouble in direct payment personal assistance relationships

Abstract

Personal assistance (PA) is a model of support where disabled people assume control of recruiting, training and managing their support staff. Direct payment relationships and symbolism borrowed from the corporate world frame PA relationships as instrumentally focused and largely free from emotional entanglements. Yet complicating this picture is research showing that PA often entails emotional dilemmas and inter-personal conflict. We report on data from 58 qualitative interviews with disabled employers and PAs. Findings reveal that PA is a deeply embedded form of work, which often requires disabled people and PAs to reconcile competing moral schemes. Applying Emerson and Messinger's (1977) micro-politics of trouble, we outline distinct causes of trouble and detail how trouble comes to be framed in either conflict resonant or deviant resonant ways. This focus on the moral dimensions of work sheds light on the relational dynamics of this prevailing model of care and embedded work more broadly.

Keywords: care work; direct payments; disability; independent living; personal assistance

Word count: 7,996

Background

Personal assistance (PA) is a model of support where disabled people assume control of recruiting, training and managing their support staff. PA differs from other forms of care, such as domiciliary care, because the disabled person is in control of how, when, and by whom they are supported. In this sense, PA is key to the disability rights movement and the philosophy of Independent Living, and variants can be found in across Europe (Mladenov, 2020).

In the UK, PA is usually made possible through direct payments – cash payments made to individuals in lieu of traditional care services – first introduced by the *Community Care (Direct Payments) Act 1996*. Direct payments mean that disabled people in receipt of welfare access cash, rather than services, and an estimated 70,000 disabled people directly employing their own staff in the UK (SFC, 2018). Typically disabled people become direct employers, meaning they are required to meet duties around pensions, paying minimum wage and statutory leave. A less common arrangement is for disabled people to enter into a contract for services with self-employed PAs. Where this happens, PAs do not have the same rights as an employee and they also assume responsibility for tax, insurance and pension arrangements. A third (and less common still) arrangement is for PAs to be employed by a third party, such as a user-led organisation (ULO) or care agency. Where this happens, PAs have rights as an employee of that agency, and employer duties are met by the agency rather than the disabled person (Woolham et al., 2019; SFC, 2018). The latter two of these arrangements share many of the characteristics of direct employment by an individual employer despite their distinctiveness in legal terms: substantial continuity of engagement with a single employer, lack of control over working times, and obeying instructions in everyday routines (Behling and Harvey, 2015). Irrespective of the model in place, the disabled person leads the process of advertising roles, conducting interviews, negotiating working arrangements, and managing everyday work practices.

Support for disabled people who employ and manage PAs is variable, and whilst some local authorities maintain a register of PAs for recruitment purposes, offer a matching service, or provide payroll and tax support, many do not. Where such services are available, they usually involve a cost to the disabled person and so uptake is varied. PA recruitment processes are therefore highly varied; some disabled people access ULO support to formulate job descriptions and conduct interviews, but many undertake these tasks independently. The freedom to lead recruitment makes highly personalised support arrangements more likely, but it can also mean disabled people face difficulties recruiting sufficient staff with appropriate skills (Glendinning et al., 2000). Support for PAs is yet more inconsistent; a recent survey of PAs (N=105) found that none were members of trade unions, and many erroneously believed that the ULO they had registered with to access employment opportunities would support them (Woolham et al., 2019). Compared to other care roles, PAs are less likely to be employed full time (31% compared to 46%); less likely to work under zero-hours contracts (17% compared to 34%); less likely to hold formal care qualifications; yet tend to earn more than their care worker counterparts (£9.10 to £7.71) (SFC 2018).

Direct payment relationships and symbolism borrowed from the corporate world frame PA relationships as commercial arrangements, instrumentally focused and largely free from emotional entanglements (Author, 2018). The role of both parties shift as the disabled person becomes an employer or manager, assuming status and power, whilst erstwhile care workers may experience concomitant losses to already fragile professional status and autonomy (Hughes et al., 2005). Further, the ability of disabled employers to remunerate PAs, in lieu of direct reciprocity, means disabled people are less susceptible to a negative imaginary surrounding dependency or the pernicious feelings of indebtedness common to informal care relationships (Fraser and Gordon, 1994). Yet complicating this picture is research showing how PA often entails emotional dilemmas and inter-personal conflict. As in other home care arrangements, disabled people and their families may struggle to adapt to having strangers in their home space, as the once private haven of home takes on the features of a public space, with care workers coming and going, governed by

institutional or commercial time constrains (Miligan and Wiles, 2010). Both parties may hold divergent and conflicting views about the extent to which they wish to share in one another's personal and social worlds (Author, 2018). For the disabled person, recruitment and retention can be further sources of stress, particularly where the PA workforce are unfamiliar with personalised approaches to support, or are from cultural backgrounds unfamiliar with independent living (Ungerson, 1999). Research has also shown that a small proportion of disabled people suffer deeply improper behaviour, such as theft and abuse, at the hands of rogue employees (Grossman et al., 2007).

The working circumstances of PAs may also be challenging, despite their relatively positive employment arrangements (SFC, 2018). Dysfunctional PA relationships have been documented and Christensen (2012) reports 'master-servant' style dynamics where the choice and control exerted by the disabled person comes directly at the expense of their PA's autonomy, thus advancing the idea that the empowerment of disabled people may come at the expense of marginalised workers in precarious work (Hughes et al., 2005). PAs often have few opportunities to undertake training or qualifications, and it is not uncommon for PAs to have no colleagues, whilst migrant workers face the added difficulty of unfamiliar working cultures (Glendenning et al., 2000). Studies of PAs in Sweden highlight distinct sources of worker dissatisfaction, including insufficient training; isolation; personal and managerial complaints with employers; a lack of control in unstructured work; and onerous levels of responsibility for the wellbeing of their employer (Wadensten and Ahlström 2011). Such situations are likely exacerbated by the fact that PAs may feel unable to express, let alone discuss, their emotions with their employers. Falch (2010) describes this scenario as PAs needing to wear an 'emotional façade' – a form of emotional labour to disguise their true feelings from the person they support.

There exists, therefore, a clear disjunction between the ideal image of PA as a commercial relationship free from emotional dilemmas, and a disparate literature charting inter-personal

conflict within PA relationships. The aim of this paper is to explore trouble within PA relationships and by highlighting the moral dimensions of the role, offer a fuller understanding of PA as an embedded form of work.

Trouble and morality in embedded work

Various models of workplace conflict and resolution exist (Frone, 2000), but the hybrid nature of PA (Ungerson, 1999) means theory tailored to the formal workplace is limited. In PA, the home space of one party becomes another's workplace; everyday tasks involve social and bodily intimacy; and typical working arrangements mean that both parties spend prolonged periods of time in one another's company, often disclosing deeply personal information about one another's lives. PA subverts normative workplace boundaries and means the relationships that ensue often resemble informal relationships, and both disabled people and PAs often describe their working relationships as akin to friendship, even family members (Author, 2018).

For these reasons, it is useful to recognise PA as a deeply embedded form of work, which is informed by interpretive schemes derived from both social and employment domains. The concept of socially embedded labour has diverse theoretical taproots, but is commonly underpinned by Polanyi's conceptualisation of labour as a 'fictitious commodity' and the theory that market economies are sustained by social relationships, political institutions, and are thus inherently moral (Polanyi, 2001). This analysis remains influential in its eschewal of a strand of economic orthodoxy, which unduly marginalises the moral dimensions of individual agency and economic action in preference of overly rationalist formulations (Bolton and Laaser, 2013). Embeddedness as popularised by Granovetter (1985), by contrast, understands economic relations as inextricably social, with attendant ethical dimensions being key to understanding economic practice. Successful and sustainable economic cooperation requires trust and the abstention from opportunism, both of which are characteristic features of informal social ties. But the moral conventions of social relations are not wholly benign, as the trust engendered by social relations may also give rise to greater opportunities for malevolent

actions, meaning harm is felt more deeply and for a longer period of time than would be the case between atomised actors (Granovetter 1985).

The centrality of trust in embedded economic action indicates social foundations, yet simply recognising the social basis of exchange relations fails to adequately incorporate moral concerns. To this end, insight may be gleaned from parallel theories of trouble within informal social relationships, which give analytic primacy to concrete social relations and the subjective, indeterminate and historically situated nature of social interaction. Emerson and Messinger's (1977) micro-politics of trouble is helpful in conceiving of relational trouble as a continuum between normal conflict and normative deviance, and so installing morality as central to explaining conflict and cooperation.

People who experience trouble in their relations with others come to define these problems in different ways. Trouble begins when one party senses dissatisfaction or disaffection towards the other, but this initial trouble does not typically escalate because it is framed in non-moralistic ways. Trouble understood in this mode is resolvable. But trouble framed moralistically – as the product of another's deviant actions or character – is much more likely to be intractable. One way that trouble is framed non-moralistically is for the troubling actions of others to be attributed to personal preferences, rather than explicit transgressions of rules – 'it's just the way they are'. Such interpretations require ongoing social relationships, and the presence of mutuality and affinity between both actors. In framing trouble this way, the troubled party perceives transgressions as being within the bounds of normal variation, within a given social tie, which affords legitimacy to the other's actions. A similar response is to interpret the actions of others as the unintended consequences of ordinary actions. This involves the tacit assumption that trouble stems incidentally from the other's pursuit of legitimate goals, rather than any malicious intention – 'they did not mean to cause offence'.

Both responses here are 'conflict-resonant' framings as they promote cycles of remedial action involving 'managerial responses' (Emerson, 2011), which aim to test the troubled party's interpretation of the trouble. If such responses fail, however, the troubled party will begin to see trouble as an indication of deeper, more sinister intentions. The troubled party may seek to isolate the troubling behaviour, and in doing so prevent moral attribution on the other. But when managerial responses are continually frustrated, the other's integrity begins to be questioned; their actions are seen as malevolent, whilst their character is revealed as untrustworthy, and ultimately, morally reprehensible. Troubling behaviours are no longer 'mistakes', but rather 'offenses', which summon indignation, anger, and even fear. Remedial responses are no longer offered nor pursued, as the troubled party acts punitively towards the offending other, and terminally towards their relationship more broadly.

[Table 1 here.]

Study methodology

The data presented in this paper are taken from an ESRC funded study into PA relationships [XXXX], which aimed to gain a deeper understanding of PA relationships, and to explore how disabled people and PAs manage challenges within these relationships. Qualitative semi-structured interviews were employed because the study was concerned with the meaning of PA relationships and how participants made sense of their experiences (Brinkmann and Kvale, 2015).

Sampling and recruitment

Disabled participants were sampled purposively through ULOs on the basis that they currently employed PAs. Four participants were actively involved in these organisations, and all were recipients of ULO communications. PA informants were recruited initially through ULOs and online forums, and later using snowball sampling. All PA participants were working as PAs at the time of their interview.

Participants recruited through ULOs were contacted by representatives from each ULO, who introduced the study and provided an information sheet and consent form. Participants recruited through snowballing, and those who responding to online study adverts, initiated contact with the research team. After making contact with the research team all participants had opportunity to ask questions about the study. The researcher ensured that each participant understood what involvement would entail. Informants gave Informed consent prior to each interview and researchers reaffirmed this after the interview had finished.

The sample of disabled participants consisted of nineteen women and eleven men; including one black-British, two white-non British, two British-Asian, and twenty-five white-British participants. The sample included a range of physical impairments, neurological disorders, musculoskeletal conditions, and three parents to children with developmental and learning disability. The sample included twenty-five individual employers; two were simultaneously individual employers who also used self-employed PAs; two managed PAs employed through a ULO; and one participant used PAs employed by her parents.

The sample of PAs consisted of twenty-two women and six men; including one black-British, three white-non British, and twenty-four white-British PAs. Twenty-five PA participants were directly employed by disabled employers (or guardians), two were self-employed, and one was employed by a ULO. Six PAs supported disabled children, the remaining PAs supported adults. The employment status and demographic status of the sample are broadly consistent with estimates of the UK PA workforce (SFC 2018; Woolham et al. 2019)

[Tables 2 & 3 here.]

Data collection and analysis

Data collection took place between 2015 and 2017 and included participants from England, Wales and Scotland. Three types of interview were offered: face-to-face, telephone, and email. Twenty-one

disabled informants took part in a face-to-face interviews (all but one of these took place in informant's own homes, with one taking place in a public space), nine took part in telephone interviews and one opted to take part in an email interview. Twenty PAs took part in telephone interviews and eight in face-to-face interviews. Telephone interviews mean that the visual features of communication are precluded, however telephone interviews offer distinct benefits including an enhanced sense of participant anonymity, meaning participants often feel more comfortable to disclose personal information. The richness of interview data, whether generated through face-to-face or telephone interviews, relies primarily on the experience and skill of the interviewer (Trier-Bieniek, 2012). In this study, each member of the research team conducted interviews and all were experienced qualitative researchers at a post-doctoral level.

Interviews followed a topic guides, which were tailored to disabled participants and PAs, but mirrored one another: both topic guides explored participants' experience of PA in a biographical context, with specific questions focusing on recruitment; training; the status of the role; ethical aspects of the role; and comparisons to other forms of care work. Interviews were transcribed verbatim and anonymised. Data storage, administration, and analysis were conducted using QSR Nvivo 11.

Constructivist Grounded Theory (Charmaz, 2014) provided a practical procedure for analysis. The first stage of coding was 'initial coding' followed by increasingly directed and conceptually driven 'focused coding'. Focused coding involved identifying and expanding the most theoretically significant and frequently occurring initial codes. A final stage of 'theoretical coding' analysed categories of codes generated through focused coding. During theoretical coding Emerson and Messinger's theory of trouble (1977) was consulted as a means of bringing coherent form and clarity at this conceptual level.

Ethical considerations

The host institution's Faculty of Medicine and Health Sciences research ethics committee provided ethical approval for the study, and whilst no particular ethical issues were encountered during data collection, the study design was shaped by two requirements of ethical approval. The first was that the study did not recruit people with learning disability or participants under the age of eighteen. This is a regrettable omission, and a limitation of this study, because PA relationships involving children or disabled people with intellectual disability are likely to be distinctive. However, there exists significant and high quality research into these kinds of relationships in the UK context (Williams et al., 2009). Another ethical requirement was that dyadic participants were not recruited, meaning disabled participants and PAs in this study did not work together. This feature of study design was required by the approving ethical committee to maintain privacy and PA autonomy.

Findings

Every participant in this study reported trouble in their PA relationships at some point in time. In the sections that follow, we outline three distinct forms of trouble: practical, personal and proximal. We then illustrate how relational troubles are framed and subsequently move in either conflict-resonant or deviant-resonant directions. Finally, we consider what these framings imply for the PA relationship as an embedded form of work. Data from disabled participants and PAs are presented in each section, and are labelled DP and PA and numbered sequentially.

Practical trouble

Practical trouble concerns instrumental processes and outcomes. Disabled informants and PAs spoke of different practical concerns, with disabled people focusing largely on the performance of their workers, and PAs emphasised working conditions and the management style of the person they worked for.

Among disabled informants, many said that practical problems were common when hiring workers with experience of traditional care roles, such as domiciliary or residential care. DP10 said that PAs with this background were less willing to take instruction: 'they seem to think they know it all already, because they've had training'. This informant spoke about a particular PA who struggled to make the transition from care home worker to PA:

'she was quite challenging to work with. She got very upset because in her experience of working in a care home she was used to having bleach and certain materials locked away in a cupboard, and of course this being a private house, I just had my bleach under the sink not locked away or anything like that' (DP10).

Informant DP06 provided another example, saying that that her direct style of management frequently caused disagreements with PAs – 'In their head I shouldn't be telling them what to do, they say "well we've been trained", I say "I don't care, you've been trained wrong"' (DP06).

PA informants also spoke of practical problems, with many raising concerns over the appropriateness of tasks. Informant PA01 provided a clear example, saying:

'I shouldn't be mending a wheelchair or mending electricity, I don't have a clue. So I say to this person "you have to call electrician, you have to call the doctor, you have to call the gardener", because it's something I don't know how to do' (PA01).

Asked whether she felt able to discuss these misgivings with her employer, PA01 said 'no, she will say "the other PA user does this, so why are you complaining about it?". Questioned about how this made her feel, PA01 replied 'It's nasty, you think you are being a bit horrible to them... maybe she just thinks I am posh that I don't want to do this'.

PAs also revealed frustrations over their employer's management style, or the fact that other people – such as the employer's partners, parents or children – were involved in their day-to-day supervision. Informant PA06 felt that he was being micromanaged by his adult employer's mother, a

situation he found both unnecessary and dispiriting: 'at lunchtime, she would call to make sure that I had arranged things in plate! It's absurd to me'. This dynamic prompted ambivalence as PA06 felt at once 'frustrated' but also feeling 'some allegiance with the user [employer] because I was in the middle of the relationships'. These frustrations stem not only from being micromanaged, but also from the micro-politics of his employer's filial relationship, and his unrealised hope that his employer should act independently of the mother. As with the forgoing examples, practical problems are not simply instrumental. Trouble originating from an employer's management style interconnects with the psycho-social dynamics of the employer's relations and home space, and play out in ways that test both parties ability to reconcile converging moral schemes informed by the world of work, the home space, and the nascent relationship between PA and the person they support.

Personal trouble

Personal trouble stems from antagonistic personalities or values. Employers and PAs spoke about personal trouble in broadly similar ways, with both identifying personality clashes and disagreements over antagonistic values or beliefs.

In one clear example, PA informant PA23 described her frustrations when working for an employer she described as emotionally immature – 'she is a very intelligent person, but emotionally, as a child'. This informant said that she had been fond of her employer, but explained that their conflicting personalities and lifecourse positions made their working relationship untenable:

'because of my knowledge... I was mother, twice divorced, I had a company. My experience was much bigger than most women my age. She was like a child, but she was my boss and I was working for her, and that was a very difficult part' (PA23).

Values were also the cause of personal trouble, and disabled employers reported clashing with PAs over issues as wide-ranging as religion, culture, and sexuality. Informant DP06 gave one example when asked she had ever sacked a PA. This informant – herself a Black British woman of Caribbean

heritage – replied; ‘yes there is an issue around culture, Afro-Caribbean culture’. DP06 said that in her experience, some PAs were more likely to hold discriminatory attitudes and beliefs about disabled people, saying ‘not all cultures are as enlightened as the UK when it comes to disabled people’. This informant explained that she tended not to employ PAs from countries where negative stereotypes of disabled people still obtain: ‘If you’ve come from a country where disabled people don’t have any rights, you’re obviously not going to be used to be working with them on an equal basis’.

Proximal trouble

Proximal trouble stems from the socio-spatial organisation of PA work, which usually involves working with a single person, often for prolonged periods of time in relatively close confines. PA informants frequently raised issues of interpersonal proximity, and informant PA19 provided a clear example when discussing the breakdown of a former relationship. This informant said that trouble with her employer had not occurred immediately, but rather ‘came over time’, saying :

‘I was spending a lot more time with her, she built in more hours, a morning and an evening thing... then she added an early morning and late evening’ (PA19).

As she spent more time with her employer, her employer grew frustrated at her continual presence, and soon became critical of her work and began acting in a passively aggressive way towards her. This ultimately led PA19 to end their relationship, and when asked whether she attributed her employer’s behaviour to the amount of time they spent together, PA19 said; ‘Yes. I do wonder if I hadn’t have done so much, whether it would have been different’.

Another PA informant, PA23, spoke of similar concerns and described her experience of PA work as a ‘kind of prison’. This informant recalled working twelve-hour shifts as a as a live-in PA, with just a single day off each week, and explained that this working pattern left her feeling isolated and without time or energy to pursue her own interests:

‘I couldn’t leave the house or do anything because at any moment she could wake up and have some need – it doesn’t work at all. So you are all the time on the standby, twenty-four hours, and that is very tiring, a mental tiredness not physical’ (PA23).

Despite efforts to restructure her working practices, PA23 ended this association because of these issues. The extent to which work had become embedded within this informant’s personal and social world was clear, as she explained; ‘being a PA, you are living somebody else’s live... I didn’t have my own life at all’.

Disabled informants also spoke of troubles arising through socio-spatial proximity, with many saying that they preferred to employ multiple PAs rather than working with just one. Informant DP07, who had employed PAs for over a decade, described how his preferred pattern of support had changed:

‘It’s kind of weird, because I have always wanted to have one person, when I was younger it made it easier, but when I got older... I found that having one person nine-until-five, every day of the week, it was difficult’ (DP07).

This participant likened the interpersonal dynamics of PA relationships to those of marriage, adding ‘I just find that I can work with someone for two or three days, but after two or three days it becomes difficult... on an emotional level’. DP07 preferred to employ four or five PAs, and to arrange his support so that each PA worked a similar number of hours. Reflecting on his experiences, this informant used a spatial metaphor to emphasise the difficulty of working with a single person;

‘you’re with someone all the time, little things... something they may forget to do – because people aren’t perfect we all make mistakes – you have to give space for that to compensate. But when you’re with someone too much, it becomes too much’ (DP07).

From normal conflict to deviant framings

All respondents in this study, both disabled informants and PAs, reported feelings of dissatisfaction or disaffection at some point in time, but the significance and consequences of this trouble varied.

At its worst, informants spoke about intractable problems and irreconcilable differences, which resulted in relationships damaged beyond repair. Less significant troubles were more common, and informants spoke frequently of relationships harmed by low-level relational problems. Left unattended, these underlying issues are likely to deepen as the intentions and character of the offending other come to be questioned. When this happens, conflict shifts from resonant framings to deviant framings, with concomitant changes in the troubled party's response, their emotions, and their interactional stance towards the other (See table 1). Emerson and Messinger's (1977) theory of trouble provides a framework for understanding this moral dimension of trouble, and by highlighting the relational and situational foundation of interpretive moral schemes, also illustrates the socially embedded nature of the role.

Conflict-resonant framings predominantly occur in response to low-level dissatisfaction, often concerning practical problems rather than personal issues. Many disabled informants spoke of PA relationships in these terms, and criticised aspects of their PA's performance, without actually confronting their PA because, on balance, their needs were being met or because mutual affinity encouraged managerial responses. DP26 provided a clear example as he expressed mild annoyance when describing his PA's performance, saying; 'he's a bit lazy, not in the personal task stuff but in other stuff. If I say 'can we fix this?' he'll say "maybe we can do it tomorrow"'. Later in his interview this informant reiterated these issues, but attributed this trouble to permissible, rather than malevolent, character traits of a PA he liked and admired; 'he's a procrastinator, in a way, but it's never bothered me too much because as long as he does his main job'.

Other disabled informants reported instances of PAs curtailing their autonomy, and whilst all found this infuriating, most framed this trouble in conflict-resonant ways and pursued managerial responses. Informant DP07 provided a clear example, and detailed a cinema trip with his PA:

'A PA of mine said "can we go to the cinema?", and I said "we can either watch 50 Shades of Grey or we can watch Birdman" and she went "oh I'm not watching 50 Shades of Grey" (DP07).

This informant accepted his PA's preference, but he soon began to question this decision 'the next day and a few days after I sat there and thought "should I be letting my PA dictate and choose what I watch?"'. In his interpretation of this encounter, this informant reveals competing moral schemes associated with the hybrid nature of PA work. As a formal care role, PAs should not impinge upon the choice and control of the disabled person they work for, yet taking account of his PA's preferences comes naturally to DP07 in relationship he labelled as 'friendly'. Reflecting on his response, DP07 stated clearly that his managerial response was intended to avoid overt conflict:

'I should have said "I am going to watch this film, we're going to watch this"... [but] I can't do that. I don't have the balls to do it. I would feel really uncomfortable' (DP07).

Typical of preliminary managerial responses, this informant attributes self-blame rather than criticising his PA, and thus avoids overt dispute. Yet what is also clear, is that the underlying dissonance between conflicting moral imperatives is unresolved; DP07 comes to resent this managerial exchange, and the relationship is harmed by ongoing trouble.

Trouble moves towards deviant resonant framings when managerial responses fail or where trouble is perceived to stem from an essential moral failing of the other. At the core of most deviant framings are concerns over safety and trust, which when breached, are near impossible to recover. This observation highlights one aspect of the embedded nature of PA work, as disabled people are typically required to share private information and personal spaces, with reciprocal admissions often granted by their PAs. Far from precluding trouble, however, such admissions mean trust is fragile and may easily be lost if either party senses that their personal safety, or that of their social world, is threatened. Informant DP20 recalled an episode during which her PA stormed out of her home in an unprecedented fit of anger; 'he just went off on one', adding 'he'd gone berserk'. This experience

left DP20 feeling isolated and vulnerable; 'it was horrible' she said, adding 'he just went and I was left again with no help'. This experience damaged an otherwise positive relationship beyond repair, as once threatened, DP20 was unwilling to allow this PA back into her home. Asked whether or not this trouble could have been resolved, DP20 said 'no, not after that'. In another example provided by a disabled informant, DP16 recalled dismissing a PA after they failed to operate hoisting equipment safely: 'he didn't know how to hoist me! He very nearly dropped me on the floor'. Understandably, this led DP16 to doubt the competence of his PA, and with his safety called into question, he ended their arrangement immediately afterwards: 'he failed twice... just too dangerous'.

Breaches in trust also precipitate deviant framings, and several disabled informants spoke of PA relationships left untenable because they no longer trusted their workers. DP19 gave a clear example as she described the breakdown of a PA relationship following the deceitful actions of her PA: 'she turned out to be absolutely awful, she stole from me and my children, told lies, and in the end we had to get the police involved'. Informant DP17 provided another example and spoke of a former PA's manipulative behaviour:

'I actually got a recording of her... just being the nastiest person I ever heard in my life, completely fabricating things and saying that I was embezzling money' (DP17).

Upon hearing this recording, DP17 dismissed her PA immediately and explained that this experience had been 'very, very intimidating'. Her abiding framing of this PA is as a morally deficient, malevolently motivated, deviant individual.

PA informants also spoke of the breakdown of PA relationships using deviant framings, and whilst less common than those reported by disabled informants, these accounts are perspicuous cases, which clearly illustrate the relational basis of moral framings. PA informant PA18 spoke about one such dispute with a long-standing employer, saying 'I met this person when I was about twenty-five, I was a PA for her when she was a parent when I was about late-thirties'. This informant explained that their relationship involved deep mutual affection, adding that she had played a central role in

assisting her employer to raise a son; 'I had enabled her to have a proper bond, I saw that as my role... to cement that bond and that connection in a positive way'. However, PA18 proceeded to recount a disagreement that followed her employer's decision to employ PA18's former partner, despite knowing theirs had been a deeply acrimonious relationship. Reflecting on this episode and the significance of her employer's actions, DP18 said 'she went and employed my ex, and it really annoyed me', adding;

'I found it very difficult... it was a bit like she chose him over me. Even though I had given her years of utter devotion and exceptional, exceptional PA support' (DP18).

Feeling betrayed, PA18 felt unable to continue working with her employer and their relationship deteriorated beyond repair. This perspicuous case illustrates the potential for PA work to become embedded within personal and social networks, with lives closely interwoven. When trouble occurs in these circumstances, the potential for relationally informed deviant framings increases, and the ensuing emotional harm is likely to be felt more deeply, and more enduringly, than would be the case between more atomised actors.

Discussion

Empowering disabled people to take charge of their support arrangements enables them to control how, when and by whom they are supported. In this sense, PA can be revolutionary and is a principal tool of independent living (Morris 1997). PA relationships are a deeply embedded form of work, which requires both parties to navigate and reconcile often conflicting moral schemes. Our focus on the ways relational troubles come to be framed in either conflict or deviant resonant ways reveals the subjective, indeterminate and historically situated nature of these relationships, whilst also speaking to embedded care and labour roles more broadly.

The PA and care literature suggests strategies that might inform practice. Personal and practical trouble may be minimised by more exacting selection of suitable staff. It is clearly preferable to match PA users with suitable PAs: this, if based on 'mutual interests and expectations' (Guldvik,

2003) will likely limit clashes over values and personalities. A probationary period is also sensible, in order to maximise the likelihood that practical arrangements and performance are agreeable to both parties. Issues over proximal conflict appear mitigated by employing several different PAs, rather than relying on a single employee. However, such strategies assume a choice of workers, which will not be the case when local labour markets fail to provide sufficient workers or employment opportunities (Grossman et al., 2007; Ungerson, 1999). Another suggestion is for disabled employers and PAs to have access to training about this unusual form of support relationship: such training could include problem solving and conflict resolution, and managing the emotion work inherent to this unique role (Matsuda et al., 2005). Other studies have emphasised the benefits of 'perceptive awareness', meaning each party needs to be able to enter into one another's role, thus achieving greater empathy and understanding (Wadensten and Ahlström, 2010). At the heart of this is respect for difference: both employer and worker need to respect one another, and be willing to accommodate some degree of difference, be that personality, values, or modes of practice. This ideal is sometimes easier to describe than to achieve, but the aforementioned strategies of vetting and probationary periods should limit pairings.

This study's sample consisted predominantly of disabled people who were individual employers and PAs who were employees. However, other models of PA exist where the disabled person uses self-employed PAs, or manages PAs employed through a third-party agency. This study included a small number participants from these latter categories, but it was not possible to draw conclusions about whether these alternate arrangements affect the relational aspects of the role. The experience of self-employed PAs appeared similar to directly employed PAs: long-standing working relations with a single disabled person, exerting limited control over their working times, and following close instruction in their everyday routines. In this sense, future research should consider if such roles represent a genuine form of self-employment (Behling and Harvey, 2015), or whether they contribute to a more diverse understanding of what self-employment means in a changing landscape of care work. For disabled people it is conceivable that managing PAs employed by a third party will

affect relational aspects of the role. If facilitated by a ULO and informed by a philosophy of independent living, such arrangements may lead to more embedded PA work given the administrative duties of being an employer are undertaken by the third party; however, if the third party employing PAs is a traditional care provider, without a genuine commitment to independent living, then the relationship will likely resemble paternalistic models of care, in which the disabled person lacks genuine choice and control. There are some indications that the latter of these employment arrangements are becoming increasingly common in the UK (Wooldham et al., 2019), and future research must consider the implications this has for PA as a distinct form of care work.

When disabled people and their PAs encounter trouble, they come to define this as either conflict to be resolved, or in moralistic terms, as the result of another's deviant character or intentions (Emerson and Messinger 1977). Our data reveal three routine forms of trouble emanating from practical, personal and proximal beginnings. The deeply embedded nature of this role makes divergent expectations within these domains more likely, as PA lacks a clear 'social script' apparent in traditional care work (Ungerson, 1999). Disabled employers may prefer PA relationships that resemble friendship, whilst PAs may desire work relations more akin to typically demarcated care roles. Alternatively, the opposite scenario is possible, and employers who prioritise performance over conviviality may encounter trouble when working with PAs who prefer relaxed working practices. Our data shows that practical trouble may often be less problematic when both parties share mutuality and affinity. In cases such as this, the transgression of expected norms around performance and working practices may be permitted in ways that would not be possible were both parties relative strangers. PA relationships may also come to resemble social ties to such an extent that they are marked indelibly by expectations and obligations derived from social and familial analogues; here the potential for hugely rewarding working relationships grows, but so too does the risk of deeply damaging personal disputes.

This variation speaks to an inherent indeterminacy within this embedded role, as moral cues depend on individual preferences shaped by a range of contextual factors including support needs, social and economic circumstances, experience of parallel care roles, and each individual's awareness of independent living as a philosophical and civil rights standpoint. This indeterminacy also means that practice solutions, such as training, must be flexible enough to accommodate difference, and should enable disabled people and PAs to reflect upon their preferred modes of working, whilst supporting them to understand the implications of these choices. Credentialism here is problematic, because of its association with professional power and paternalistic models of care, and also the fact that many disabled people simply prefer to train their own PAs in order to achieve personalised support. However, there is clear scope for training that is co-produced with disabled people and PAs, which prepares both parties for the distinctive relational challenges, and rewards, this role offers.

In the UK, the lack of support for disabled people and PAs is striking; where support is available (such as training or payroll services), this usually involves a cost to the disabled person. Formal support for PAs is yet more inconsistent as PAs tend not to be members of trade unions (Woolham et al., 2019), and where training for PAs is available, access is often contingent upon the disabled person meeting any costs. A small number of disabled people in this study said that managing the interpersonal aspects of the role were simply too onerous, and as a result, stated their preference for agency provided domiciliary care. This is regrettable if these choices result from a paucity of accessible support, rather than a genuine expression of choice and control. Support for disabled people and PAs must therefore be acknowledged, transparently costed and appropriately funded by state care settlements if the right to independent living is to become a reality rather than lofty ambition.

Conclusion

PA is a transformational model of support where disabled people assume control of recruiting, training and managing the staff that support them. A deeply embedded form of care work, PA often requires disabled people and their PAs to reconcile competing moral schemes derived from the

world of work, but also from concrete social relations that are inherently subjective, indeterminate and historically situated. Relational trouble in the PA relationship is framed and subsequently moves in either conflict-resonant or deviant-resonant directions. Trouble framed moralistically – as the product of another’s deviant actions or character – is much more likely to be intractable. Supporting disabled people and PAs to understand their relational preferences, and the expectations and obligations these choices involve, is needed if both parties are to realise the rewards, and avoid the risks, inherent to this embedded form of care work.

Tables

Table 1: Typology of trouble adapted from Emerson (2011)

	Conflict-resonant	Deviance-resonant
Nature of the trouble	Normal, pragmatic, means-oriented	Serious, moralistic, essence-oriented
Definitions of the act	Hassle, bother, mistake, normal variation	Misconduct, wrongdoing, offense
Emotions	'small' emotions: annoyance, frustration, upset	Moral emotions: humiliation, indignation, anger
Trouble party's interactional stance	Normalising, equalising, civil proposals	Alienating, hierarchical, interactional stance exaggerating/dramatizing difference
Other's reaction	Credible remedial work, accounts, apologies, compliance with proposal	Flagrant repetition; no ritual work, or ritual work seen to be empty
Nature of responses	Unilateral/managerial; corrective, remedial, inviting compromise and negotiation	Deep avoidance and/or exit; punitive, name-calling, alienating
